**Relative Contraindications of Platelet Transfusion**
- TTP, HIT, post-transfusion purpura, HELLP

---

**American Society of Hematology**

Choosing Wisely Recommendation

Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe hemoglobin range (70-90 g/L) in stable non-cardiac patients

**Transfusion Requirements in Critical Care (TRICC)**

NEJM 1999;340:409-417

Study: Multicentre, RCT.

Participants: 838 critically ill patients with euvolemia after initial treatment and hemoglobin less than 9 g/dL, within 72 h of ICU admission.

Intervention: Patients receiving a transfusion followed either (1) a restrictive strategy (RS; n=418) in which red cells were transfused if hemoglobin was less than 7.0 g/dL, and then maintained at 7 to 9 g/dL or (2) a liberal strategy (LS; n=420) in which transfusions occurred when the hemoglobin was less than 10.0 g/dL. and then maintained at 10 to 12 g/dL.

Primary Outcome: Mortality at 30 d and severity of organ dysfunction.

Results: Mortality rates at 30 d were similar between groups. However, mortality rates were significantly lower with the RS among less acutely ill patients (8.7% RS and 16.1% in LS group; p=0.03) and among those <59 yr of age (5.7% RS and 13% in LS; p=0.02), but did not differ in a subgroup with clinically significant cardiac disease.

Conclusion: A RS of red cell transfusion is at least as effective as, and possibly superior to, a LS transfusion in critically ill patients.

---

**Liberal or Restrictive Transfusion in High-Risk Patients After Hip Surgery (FOCUS)**

NEJM 2011;365:2453-2462

Study: Multicentre RCT.

Participants: 2,016 patients aged greater than 50 yr with a history of or risk factors for cardiovascular disease and hemoglobin (Hb) level below 10 g/dL after hip fracture surgery.

Intervention: Patients were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL). Primary Outcome: Mortality or inability to walk across a room without human assistance on a 60 day follow-up.

Results: Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups.

Conclusion: A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 d follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.
Coagulation Factors

Table 39. Coagulation Factor Products

<table>

Acute Blood Transfusion Reactions

IMMUNE

Acute Hemolytic Transfusion Reactions

- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1 in 40,000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - maintain BP with vigorous IV fluids ± inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions

- due to alloantibodies to WBC, platelets or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 0-6 h of transfusion
- risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- presents with fever ± rigors, facial flushing, headache, myalgia, hypotension
- treatment
  - rule out hemolytic reaction or infection
  - if temperature <38°C, continue with transfusion but decrease rate and give antipyretics
  - if temperature >38°C, stop transfusion, give antipyretics and anti-histamine

Allergic Nonhemolytic Transfusion Reactions

- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1 in 100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenhydramine, steroids, epinephrine, IV fluids, and bronchodilators

Transfusion-Related Acute Lung Injury

- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - insidious, acute onset of pulmonary insufficiency
  - profound hypoxemia (PaO₂/FiO₂ <300 mmHg)
  - bilateral pulmonary edema on CXR
  - pulmonary artery wedge pressure <18 mmHg
  - no clinical evidence of left atrial hypertension
  - pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
  - typically occurs 2-4 h post transfusion and resolves in 24-72 h
  - risk per unit of blood is 1 in 10,000
  - is currently the leading cause of transfusion-related morbidity and mortality
  - treatment: supportive therapy (oxygen)
  - inform blood bank; patient and donor testing will be arranged
NONIMMUNE

Transfusion-Associated Circulatory Overload
- due to impaired cardiac function and/or excessive rapid transfusion
- presentation: dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung, and increased venous pressure
- incidence: 1 in 700 and is becoming more common
- treatment: transfuse at lower rate, give diuretics and oxygen

Bacterial Infection
- Gram positive: *S. aureus, S. epidermidis, Bacillus cereus*
- Gram negative: *Klebsiella, Serratia, Pseudomonas, Yersinia*
- overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

Hyperkalemia
- due to K+ release from stored RBC
- risk increases with storage time and if blood is irradiated and risk decreases if given fresh blood
- occurs in 5% of massively transfused patients
- treatment: see Nephrology, NP12

Citrate Toxicity
- occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to Ca^{2+} and causes signs and symptoms of hypocalcemia
- treatment: IV calcium gluconate (10 mL for every 2 units of blood)

Dilutional Coagulopathy
- occurs with massive transfusion (>10 units)
- pRBC contains no clotting factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, cryoprecipitate, and platelets

Delayed Blood Transfusion Reactions

IMMUNE

Delayed Hemolytic
- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
- occurs 5-7 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion

Transfusion-Associated Graft Versus Host Disease
- transfused T-lymphocytes recognize and react against “host” (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

NONIMMUNE

Iron Overload
- due to repeated transfusions over long period of time (e.g. β-thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

Viral Infection Risk
- HBV <1 in 153,000
- Human T-lymphotropic virus (HTLV) <1 in 4,300,000
- HCV <1 in 2,300,000
- HIV <1 in 7,000,000
- other infections include EBV, CMV, WNV (West Nile virus)
### Antiplatelet Therapy

<td>GI upset, Dyspepsia</td>
<td>Only indicated for AFT in Canada Contraindicated in renal failure, cancer patients, mechanical heart valves</td>
</tr>
</tbody>
</table>

### Adverse Reactions of Heparin
- Hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- Heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 22, H29)
- Osteoporosis: with long-term use

### Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)
- Increased bioavailability compared to normal heparin
- Increased duration of action
- SC route of administration
- Do not need to monitor aPTT
- Adverse reactions less common than UFH
- Patients with renal failure (CrCl <30) can accumulate LMWH, therefore must adjust dose
- Only partially reversible with protamine sulfate

Bacteria Basics

- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - Gram positive (GP): thick, rigid layer of peptidoglycan
  - Gram negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipopolysaccharides
- clinical significance: GN thick outer membrane makes it resistant to penicillin's mechanism of action
- acid-fast bacilli (AFB): high mycolic acid content in cell wall, "acid fast" as washout phase with acid-alcohol is ineffective in acid-fast bacteria, e.g. Mycobacteria, Nocardia
- *atypical* bacteria: not seen on Gram stain and difficult to culture
- obligate intracellular bacteria: e.g. Chlamydia, Chlamyphilia
- bacteria lacking a cell wall: e.g. Mycoplasma
- spirochetes: e.g. Treponema pallidum
- O₂ can be either vital or detrimental to growth
- obligate aerobes: require O₂
- obligate anaerobes: require environment without O₂
- facultative anaerobes: can survive in environments with or without O₂

Mechanisms of Bacterial Disease

1. adherence to and colonization of skin or mucous membranes
   - e.g. fimbiae (pili): microfilaments extending through the cell wall – like burrs sticking to your clothes, they attach to epithelial cells e.g. E. coli in the urinary tract
2. invasion or crossing normal epithelial barriers
3. evasion of host defense system through inhibition of
   - phagocytic uptake via polysaccharide capsule (S. pneumoniae, N. meningitidis, H. influenzae) or surface proteins (Staphylococcus, Streptococcus)
4. toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. Clostridium)
   - endotoxins are structural components of GN bacterial cell walls, and may be shed by live cells or released during cell lysis
5. intracellular growth
   - obligate intracellular: Rickettsia, Chlamydia, Chlamyphilia
   - facultative intracellular: Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella
6. biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. S. epidermidis) which can coat prosthetic devices like IV catheters

Figure 2. Laboratory identification of bacterial species
Virology

Viral Basics
- Viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - Infect cells and use host metabolic machinery to replicate
  - Nucleic acid can be double stranded (ds) or single stranded (ss)
  - Can be enveloped or naked
- Virions are mature virus particles that can be released into the extracellular environment
- Host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns
1. Acute infections (e.g. adenovirus)
   - Host cells are lysed in the process of virion release
   - Some produce acute infections with late sequelae (e.g. measles virus → subacute sclerosing panencephalitis)
2. Chronic infections (>6 mo): (e.g. HBV, HIV)
   - Host cell machinery is used to produce and chronically release virions
3. Latent infections
   - Viral genome remains latent in host cell nucleus
   - Can reactivate (e.g. HSV, VZV)

Mycology

Fungal Basics
- fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. molds (also known as filamentous fungi) (multicellular with hyphae)
  3. dimorphic fungi (found as mold at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

<tr>
<td>Bacteria</td>
<td>Peptidoglycan</td>
</tr>
<tr>
<td>Human Cell</td>
<td>Cholesterol</td>
</tr>
<tr>
<td>Fungi</td>
<td>Ergosterol, Chitin</td>
</tr>
</tbody>
</table>

Mechanisms of Fungal Disease
- primary fungal infection by
  - overgrowth of normal flora (e.g. Candida species)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics
- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 26 and 27 for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

<table>
<thead>
<tr>

</tr>
<tr>
<td>Eosinophilia unusual</td>
<td>Eosinophilia (proportional to extent of tissue invasion)*</td>
</tr>
<tr>
<td>Indefinite life span</td>
<td>Definite life span</td>
</tr>
</tbody>
</table>

*Adult Ascaris (roundworm) does not cause eosinophilia; migratory larval phases of Ascaris, however, cause high-grade eosinophilia

Characteristics of Parasitic Disease
- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease
1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B12 deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
  - acute hypersensitivity (e.g. pneumonitis in Loeffler’s syndrome)
  - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
  - cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
  - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
  - immune complex (e.g. nephritis of malaria, schistosomiasis)
### Transmission of Infectious Diseases

### Nosocomial Infections

- **nosocomial infection**: infections acquired >48 h after admission to a healthcare facility or within 30 d from discharge
- risk factors: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

**Table 7. Common Nosocomial Infectious Agents**

Respiratory Infections

Pneumonia

- see *Pediatrics*, P88
- see *Family Medicine*, FM20

**Definition**

- infection of the lung parenchyma

**Etiology and Risk Factors**

- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
- impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)

- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

**Table 8. Common Organisms in Pneumonia**

</tbody>
</table>

*See *Pediatrics* P90, Table for Common Causes and Treatment of Pneumonia at Different Ages

**Clinical Features**

- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion) (see Respiratory R23)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage
Investigations
- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
- sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for
  1. (1) severely ill patients refractory to treatment and (2) immunocompromised patients

Treatment
- ABC, O₂, IV fluids, consider salbutamol (nebulized or MDI)
- determine prognosis and need for hospitalization and antibiotics

</tr>
<tr>
<td>Late onset disease (≥5 d) or With risk factors for MDR:</td>
<td>Antipseudomonal cephalosporin (ceftepipe or ceftazidime) OR antipseudomonal carbapenem (imipenem or meropenem) OR β-lactam/β-lactamase inhibitor (piperacillin/tazobactam) PLUS</td>
</tr>
</tbody>
</table>

Note: Always use directed therapy against specific organism if one is found on culture (e.g. blood, sputum, etc.)
Note: These guidelines may be less applicable in Canada given lower rates of antibiotic resistance among common nosocomial pathogens

Prevention
- Public Health Agency of Canada recommends the following
  1. Vaccine for influenza A and B annually for all ages ≥ 6 mo
  2. Pneumococcal polysaccharide vaccine (Pneumovax®) for all adults ≥ 65 yr and younger patients 24 mo of age and older at high risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
pneumococcal conjugate vaccine (Prevnar-13®) for all children <5 yr, and for children and adolescents at high risk for invasive pneumococcal disease who are 5-17 yr and who have not previously received Prevnar-13® (CDC recommends giving Prevnar-13® to all adults at high risk for invasive pneumococcal disease)

### Influenza

**Definitions and Etiology**
- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins: hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: human-origin A (H1N1) and B (H3N2) subtypes
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
- outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
- antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

**Clinical Features**
- incubation period 1-4 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, H/A, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)

**Investigations**
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for rapid antigen detection, DFA (Direct Fluorescent Antigen) detection, RT-PCR (gold standard)
- serology: rarely used for clinical management

**Treatment and Prevention**
- primarily supportive unless severe infection or high-risk of complications (e.g. elderly, pulmonary or cardiac disease)
- neuraminidase inhibitors: zanamivir (Relenza®) and oseltamivir (Tamiflu)® for treatment and prophylaxis against types A and B
  - decreases duration (by 1-2 d) and severity of symptoms if given within 48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- M2-inhibitors: amantidine/rimantidine for treatment and prophylaxis against type A only no longer recommended due to increased resistance
- vaccine for influenza A and B viruses is recommended annually for all ages ≥6 mo
- vaccine is reformulated each year to reflect circulating influenza A and B strains

### Cellulitis

**Definition**
- acute infection of the skin principally involving the dermis and subcutaneous tissue
Etiology
- common causative agents: *S. aureus*, β-hemolytic streptococci
- immunocompromised patients or water exposure: may also include GN rods and fungi
- risk factors
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema DM, cracked skin in feet/toes (tinea pedis)

Clinical Features
- pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
- CBC and differential, blood C&S if febrile
- skin swab ONLY if open wound with pus

Treatment
- antibiotics: cephalaxin (broader coverage if risk factors for GN rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- if MRSA is suspected, alternative therapy should be prescribed (see *A Simplified Look at Antibiotics*, ID47)
- limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
- life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
- Two main forms
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus*, *Bacteroides*, *Enterobacteriaceae*)
  - Type II: monomicrobial infection with GAS, and less commonly *S. aureus*

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
- edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
- infection spreads rapidly
- patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae

Investigations
- clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum CK (elevated CK usually means myonecrosis – a late sign)
- plain film x-ray (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

Treatment
- resuscitation with IV fluids
- emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin
  - if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): cefazolin (or cloxacillin) + clindamycin IV; with confirmed GAS infection, penicillin G + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

Gastrointestinal Infections

Acute Diarrhea
- see *Gastroenterology*, G15
- see *Pediatrics*, P35
Epidemiology
• one of the top five leading causes of death worldwide, according to the World Health Organization
• significant morbidity in developed countries (over 900,000 hospitalizations in the United States each year)

Definition
• passage of ≥3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤14 d

Approach to Acute Diarrhea
• rationale
  ▪ the vast majority of acute diarrhea is caused by infection
  ▪ in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
  ▪ investigations are costly and are necessary only in certain circumstances
• therefore, the evaluation of acute diarrhea involves
  ▪ identifying characteristics of the illness or patient that warrant further investigation
  ▪ assessing volume status to determine appropriate method of rehydration
• see Figure 7

Physical Exam
• volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
• abdominal exam: pain, guarding, peritoneal signs

Treatment
• rehydration is mainstay of treatment
  ▪ oral rehydration therapy
  ▪ IV rehydration if oral intake insufficient to replace fluid loss
• antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
  ▪ delays excretion of causative pathogens
  ▪ contraindications: diarrhea with fever, bloody stool or diarrhea caused by C. difficile
• antibiotic therapy is rarely indicated because
  ▪ most acute diarrheal illness is viral and self-limited
  ▪ antibiotics can eradicate normal gut flora, predisposing patient to C. difficile infection
  ▪ antibiotics prolong the shedding of Salmonella and other causes of bacterial diarrhea
  ▪ in EHEC infection, antibiotics may increase the risk of HUS
  ▪ indications for antibiotic therapy are shown in Figure 7

Figure 7. Approach to acute diarrhea

Causes of Acute Bloody Diarrhea
Campylobacter
Hemorrhagic E. coli (e.g. O157:H7)
Entamoeba histolytica
Salmonella
Shigella

Traveller’s Diarrhea

- see Acute Diarrhea, ID10

Epidemiology
- most common illness to affect travellers
- up to 50% of travellers to developing countries affected in first 2 wk and 10-20% after returning home

Etiology
- bacterial (80-90%): E. coli most common (ETEC), Campylobacter, Shigella, Salmonella, Vibrio (non-cholera); wide regional variation (e.g. Campylobacter more common in Southeast Asia)
- viral: norovirus, rotavirus, and astrovirus account for 5-8% * protozoal (rarely): Giardia, Entamoeba histolytica, Cryptosporidium, and Cyclospora for ~10% in long-term travellers
- pathogen-negative traveller’s diarrhoea common despite exhaustive microbiological workup

Treatment
- rehydration is the mainstay of therapy
  - rehydrate with sealed beverages
  - in severe fluid loss use oral rehydration solutions (1 package in 1 L boiled or treated water)
- treat symptoms: anti diarrheal agents (e.g. bismuth salicylate, loperamide)
- empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
- note: there is increasing fluoroquinolone resistance in causative agents, especially in Southeast Asia

Prevention
- proper hygiene practices
  - avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  - avoid untreated water
- bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
- CDC Guidelines: antibiotic prophylaxis not recommended
- increased risk of infection with resistant organisms
- high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents

Bismuth salicylate (Pepto-Bismol®) can cause patients to have black stools, which may be mistaken for melena
• Dukoral®: oral vaccine that offers protection against *V. cholerae* (efficacy ~80%) and ETEC (efficacy ~50-67%). Not recommended for routine use in travellers, but the PHAC recommends that it may be considered in short-term travellers >2 yr old who are high-risk (e.g. chronic illness) for whom there is an increased risk of serious consequences for traveller’s diarrhea (e.g. chronic renal failure, CHF, type 1 DM, inflammatory bowel disease), immunosuppressed, history of repeat traveller’s diarrhea, increased risk of acquiring traveller’s diarrhea (gastric hypochlorhydria or young children >2 yr), or travellers to cholera endemic countries at increased risk of exposure.

### Chronic Diarrhea
- see Gastroenterology, G16

### Peptic Ulcer Disease *(H. pylori)*
- see Gastroenterology, G12

### Bone and Joint Infections

#### Septic Arthritis

**Routes of Infection**
- hematogenous
- contiguous osteomyelitis common in children
- direct inoculation via skin/trauma
- iatrogenic (surgery, arthroscopy, arthrocentesis)

**Etiology**
- gonococcal
  - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
  - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  - *Streptococcus* species (Group A and B)
  - Gram-negatives: affect neonates, elderly, IV drug users, immunocompromised
  - *S. pneumoniae*: affects children
  - *Kingella kingae*: affects children aged <2 yr of age
  - *Haemophilus influenzae* type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
  - *Salmonella* spp.: characteristic of sickle cell disease
  - coagulase-negative *Staphylococcus* species: prosthetic joints
  - if culture negative: partially-treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as *Borrelia* spp. (Lyme disease) or *Tropheryma whipplei* (Whipple’s disease), and non-infectious causes

**Risk Factors**
- gonococcal
  - age (<40 yr), multiple partners, unprotected intercourse, MSM
- non-gonococcal
  - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
  - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  - prosthetic joints/recent joint surgery
  - underlying joint disease (rheumatoid arthritis, osteoarthritis)
  - immunocompromise (DM, chronic kidney disease, alcoholism, cirrhosis)
  - loss of skin integrity (cutaneous ulcer, skin infection)
  - age >80 yr

**Clinical Features of Gonococcal Arthritis**
- two forms (although often overlap)
  - bacteremic form
    - systemic symptoms: fever, malaise, chills
    - gonococcal triad: migratory polyarthralgias, tenosynovitis, dermatitis (pustular skin lesions)
  - septic arthritis form
    - local symptoms in involved joint: swelling, warmth, pain, inability to bear weight, marked decrease in range of motion (see Rheumatology, RH3 for differential diagnosis)

**Clinical Features of Non-Gonococcal Arthritis**
- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

### Medical Emergency
Septic arthritis is a medical emergency! If untreated, rapid joint destruction will occur.

### Disseminated Gonococcal Infection Triad
- Migratory arthralgias
- Tenosynovitis next to inflamed joint
- Pustular skin lesions
Investigations
- consider rheumatologic causes for monoarthritis (see Rheumatology, RH3)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15,000/mm³: likelihood of infection increases with increasing WBCs), PMNs >90%, culture positive
  - growth of N. gonorrhoeae from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Treatment
- medical
  - empiric IV antibiotics: specific choice depends on clinical scenario; for most adults, vancomycin + ceftriaxone is reasonable; for fully vaccinated children, cefazolin or clonacillin IV unless MRSA is a consideration – delay may result in joint destruction
  - Gram stain and cultures guide subsequent treatment
  - gonococcal: ceftriaxone + azithromycin, for concurrent treatment of C. trachomatis
  - non-gonococcal: antibiotics against Streptococcus spp. (2-3 wk IV f/b PO), S. aureus (4 wk IV minimum), or GNB (4 wk)
- surgical drainage if (see Orthopedics, OR10)
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement
  - prosthetic joint
- daily joint aspirations until culture sterile; no need to give intra-articular antibiotics
- physiotherapy

Prognosis
- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

Diabetic Foot Infections
Etiology
- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: S. aureus, Streptococcus spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (S. aureus, Streptococcus, Enterococcus, GNB) and anaerobes (Peptostreptococcus, Bacteroides, Clostridium)

Clinical Features
- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) or the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations
- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI if high clinical suspicion
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment
- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalaxin or clindamycin
- moderate: clindamycin + ciprofloxacin or moxifloxacin PO, ceftriaxone or ertapenem IV ± MRSA coverage
- severe: piperacillin/tazobactam or meropenem IV ± vancomycin if MRSA known or suspected
- encourage glycemic control

Does this Patient with Diabetes have Osteomyelitis of the Lower Extremity? JAMA 2008;299:906-913
Study: Systematic literature review, 21 studies.
Population: 1,027 adult patients with DM being investigated for osteomyelitis.
Intervention: Various aspects of history, physical exam, laboratory tests, and diagnostic imaging studies versus bone biopsy.
Primary Outcome: Diagnostic utility.
Results: No studies examined any part of history taking. Temperature, ulcer characteristics (erythema, swelling, purulence), elevated WBC, skin swabs, and soft tissue cultures were not useful. Nuclear imaging has poor specificity for osteomyelitis (62%-89.5%), and MRIs have greater accuracy in detecting osteomyelitis.

*NS = not significant
**Osteomyelitis**
- see Orthopedics, OR10

**Cardiac Infections**

**Infective Endocarditis**

**Definition**
- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

**Risk Factors and Etiology**
- predisposing conditions
  - **high risk**: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - **moderate risk**: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - **low/no risk**: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, ischemic heart disease, previous CABG
- frequency of valve involvement MV >> AV > TV > PV
  - but in 50% of IVDU-related IE the tricuspid valve is involved

**Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors**

Organisms in bold are the most common isolates.
1. Streptococcus includes mainly viridans group streptococci
2. Other includes less common organisms such as:
   - Streptococcus pneumoniae (previously known as S. pneumoniae, usually associated with underlying GI malignancy, cirrhosis)
   - Culture-negative organisms including nutritionally-deficient streptococci, HACEK, Bartonella, Coxiella, Chlamydia, Legionella, Brucella
   - Candida
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = Pseudomonas, saliva = oral flora, toilet water = GI flora)

**Clinical Features**
- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute MR, AR)
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), H/A (myotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler’s nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth’s spots (retinal hemorrhage with pale centre)

**Diagnosis**
- Modified Duke Criteria, see Table 17
  - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  - possible diagnosis if: 1 major + 1 minor, OR 3 minor
Table 17. Modified Duke Criteria

**Major Criteria (2)**

1. Positive blood cultures for IE
   - Typical microorganisms for IE from 2 separate blood cultures (Streptococcus viridans, HACEK group (see ID16), Streptococcus gallolyticus (previously known as S. bovis), Staphylococcus aureus, community-acquired enterococci) OR
   - Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart OR
   - All of 3 or a majority of 4 or more separate blood cultures, with first and last drawn >1 h apart OR
   - Single positive blood culture for Coxiella burnetii or antiphase IgG antibody titer >1:800

2. Evidence of endocardial involvement
   - Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternate anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve) OR
   - New valvular regurgitation (insufficient if increase or change in preexisting murmur)

**Minor Criteria (5)**

1. Predisposing condition (abnormal heart valve, IVDU)
2. Fever (38.0°C/100.4°F)
3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions
4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler’s nodes, Roth’s spots
5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

**Investigations**

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48 to 72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), BUN/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- Echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

**Treatment**

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken
    - first-line empiric treatment for native valve: vancomycin + gentamicin OR ceftriaxone
    - first line empiric treatment for prosthetic valve: vancomycin + gentamicin + cefepime + rifampin
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and sensitivities
  - monitor for complications of IE (e.g. CHF, conduction block, new emboli) and complications of antibiotics (e.g. interstitial nephritis)
  - prophylaxis only for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue
    - dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if penicillin-allergic
    - skin/soft tissue: cephalexin single dose 30-60 min prior; clindamycin if penicillin-allergic (modify based on etiology of skin/soft tissue infection)
  - surgical
    - most common indication is refractory CHF
    - other indications include: valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, Streptococci on a prosthetic valve

**Prognosis**

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess
- mortality: prosthetic valve IE (25-50%), non-IVDU S. aureus IE (30-45%), IVDU S. aureus or streptococcal IE (10-15%)
Meningitis

- see Pediatrics, P60

Definition
- inflammation of the meninges

Etiology

Table 18. Common Organisms in Meningitis

Risk Factors
- lack of immunization against S. pneumoniae, H. influenzae type b in children
- hematogenous spread after invasion from a mucosal surface (nasopharynx)
- parameningeal focus (otitis media, infection, sinusitis)
- penetrating head trauma
- anatomical meningeal defects – CSF leaks
- previous neurosurgical procedures, shunts
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

Clinical Features
- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, H/A, neck stiffness, confusion, lethargy, altered level of consciousness, seizures, focal neurological signs, N/V, photophobia, papilledema
- petechial rash in meningococcal meningitis, seen more frequently on trunk or lower extremities

Investigations
- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
- AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
- PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
- WNV serology in blood and CSF during summer and early fall if viral cause suspected
- Listeria monocytogenes – GN diplococci
- H. influenzae – Pleomorphic GN coccobacilli
- L. monocytogenes – GP rods
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
- PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
- WNV serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

Treatment
- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
  - age <6 wk: ampicillin + cefotaxime IV OR ampicillin ± an aminoglycoside IV; add vancomycin if suspect S. pneumoniae
  - 6 wks-3 mo: ampicillin + cefotaxime + vancomycin
  - age >3 mo: vancomycin + cefotaxime or ceftriaxone IV
  - add ampicillin IV if risk factors for infection with L. monocytogenes present: age >50, alcoholism, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
- continue in those patients with proven pneumococcal meningitis
- not recommended for patients with suspected bacterial meningitis in some resource-limited countries
- not recommended for neonatal meningitis

Risk Factors
- lack of immunization against S. pneumoniae, H. influenzae type b in children
- hematogenous spread after invasion from a mucosal surface (nasopharynx)
- parameningeal focus (otitis media, infection, sinusitis)
- penetrating head trauma
- anatomical meningeal defects – CSF leaks
- previous neurosurgical procedures, shunts
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

Clinical Features
- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, H/A, neck stiffness, confusion, lethargy, altered level of consciousness, seizures, focal neurological signs, N/V, photophobia, papilledema
- petechial rash in meningococcal meningitis, seen more frequently on trunk or lower extremities

Investigations
- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
- AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure

Treatment
- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
  - age <6 wk: ampicillin + cefotaxime IV OR ampicillin ± an aminoglycoside IV; add vancomycin if suspect S. pneumoniae
  - 6 wks-3 mo: ampicillin + cefotaxime + vancomycin
  - age >3 mo: vancomycin + cefotaxime or ceftriaxone IV
  - add ampicillin IV if risk factors for infection with L. monocytogenes present: age >50, alcoholism, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
- continue in those patients with proven pneumococcal meningitis
- not recommended for patients with suspected bacterial meningitis in some resource-limited countries
- not recommended for neonatal meningitis
Prevention
• see Pediatrics, P3
• immunization
  ♦ children: immunization against H. influenzae type B (Pentacel®), S. pneumoniae (Synflorix®, Prevnar-13®), N. meningitidis (Menjugate®, Menactra®, Bexsero®)
  ♦ adults: immunization against N. meningitidis in selected circumstances (outbreaks, travel, epidemics) and S. pneumoniae (Pneumovax®) for high-risk groups
• prophylaxis: close contacts of patients infected with H. influenzae type B should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with N. meningitidis

Prognosis
• complications
  • H/A, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness, death
• mortality
  • S. pneumoniae 25%; N. meningitidis 5-10%; H. influenzae 5%
• worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

Encephalitis

Definition
• inflammation of the brain parenchyma

Etiology
• identified in only 40-70% of cases
  • when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, West Nile, HIV, mumps, measles, rabies, polio
  • bacteria: L. monocytogenes, Mycobacteria, spirochetes (Lyme, syphilis), Mycoplasma pneumoniae
  • parasites: protozoa (e.g. Toxoplasma) and helminths (rare)
  • fungi: e.g. Cryptococcus
  • post-infectious (e.g. acute disseminated encephalomyelitis [ADEM])
  • auto-antibody mediated encephalitis
    • anti-N-methyl-D-aspartate (NMDA) receptor encephalitis most common
    • in adults, most autoantibody-mediated encephalitis cases are associated with malignancy

Pathophysiology
• acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
• viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
• herpes simplex encephalitis
  • acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
  • associated with HSV-1, but can also be caused by HSV-2
• influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

Clinical Features
• constitutional: fever, chills, malaise, N/V
• meningeval involvement (meningoencephalitis): H/A, nuchal rigidity
• parenchymal involvement: seizures, altered mental status, focal neurological signs
• herpes simplex encephalitis
  • acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  • temporal lobe involvement: behavioural disturbance
  • usually rapidly progressive over several days and may result in coma or death
  • common sequelae: memory and behavioural disturbances

Investigations
• CSF: opening pressure, cell count and differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, S. pneumoniae, and selectively for other less common etiologies
• serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rabies, Bartonella henselae)
• imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behaviour, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes (“meningoencephalitis”)
• invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
  • findings in herpes simplex encephalitis (must rule out due to high mortality)
    ▪ CT/MRI: medial temporal lobe necrosis
    ▪ EEG: early focal slowing, periodic discharges

Treatment
• general supportive care
• monitor vital signs carefully
• IV acyclovir empirically until HSV encephalitis ruled out

Generalized Tetanus

• see Pediatrics, P4

Etiology and Pathophysiology
• caused by Clostridium tetani: motile, spore forming, anaerobic GP bacillus
• found in soil, splinters, rusty nails, GI tract (humans and animals)
• traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, nonsterile surgeries or deliveries)
• upon inoculation, spores transform into C. tetani bacilli that produce tetanus toxin
  ▪ toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  ▪ net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

Clinical Features
• generalized tetanus
  ▪ initially present with painful spasms of masseters (trismus or "lockjaw")
  ▪ sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  ▪ paralysis descends to involve large muscle groups (neck, abdomen)
  ▪ apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
• autonomic hyperactivity
  ▪ diaphoresis, tachycardia, HTN, fever as illness progresses

Investigations
• primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
• culture wounds, CK may be elevated

Treatment
• stop toxin production
  ▪ wound debridement to clear necrotic tissue and spores
  ▪ antimicrobial therapy: IV metronidazole; IV penicillin G is an effective alternative
  ▪ neutralize unbound toxin with tetanus immune globulin (TIG)
  ▪ supportive therapy: intubation, spasmylytic medications (benzodiazepines), quiet environment, cooling blanket
  ▪ control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

Prevention
• infection with C. tetani does not produce immunity – vaccinate patients on diagnosis
• tetanus toxoid vaccination (see Pediatrics, P4 and Emergency Medicine, ER17)

Rabies

Definition
• acute progressive encephalitis caused by RNA virus (genus Lyssavirus of the Rhabdoviridae family)

Etiology and Pathophysiology
• any mammal can transmit the rabies virus
  ▪ most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
  ▪ transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  ▪ almost all cases due to bites
  ▪ virus travels via retrograde axonal transport from PNS to CNS
  ▪ virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
  ▪ development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
    ▪ infected animal can transmit rabies virus as soon as it shows signs of disease
Clinical Features
• five stages of disease
  1. incubation period
     • 1-3 mo on average (can range from days to years)
  2. prodrome (<1 wk)
     • influenza-like illness: low-grade fever, malaise, anorexia, N/V, H/A, sore throat
     • pain, pruritus, and paresthesia may occur at wound site
     • once prodromal symptoms develop, there is rapid, irreversible progression to death
       • progression from prodrome to coma and death may occur without an intervening acute
         neurologic syndrome
  3. acute neurologic syndrome: 3 types (<1 wk)
     a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia,
        hypersalivation, fever, seizures
        • painful pharyngeal spasms on encountering gust of air or swallowing water cause
        aerophobia and hydrophobia, respectively
     b. paralytic: quadriplegia, loss of anal sphincter tone, fever
     c. atypical: rare
  4. coma
     • complete flaccid paralysis, respiratory and cardiovascular failure
  5. death (within days to weeks of initial symptoms)

Investigations
• purpose of diagnosis by investigations is to limit patient contact with others and to identify
  others exposed to the infectious source
• ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy,
  serum, CSF
• post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion
  bodies in neurons)

Treatment
• post-exposure prophylaxis depends on regional prevalence (contact Public Health) and
  circumstances surrounding injury
• 3 general principles
  • wound care: clean wound promptly and thoroughly with soap and running water
  • passive immunization: HRIg infiltrated into wound site, with any remaining volume
    administered IM in anatomical site distant from vaccine administration
  • active immunization: inactivated human diploid cell rabies virus vaccine (series of 4 shots
    post-exposure if not pre-immunized)
• treatment is supportive once victim manifests signs and symptoms of disease

Prevention
• pre-exposure vaccination
  • recommended for high risk persons: laboratory staff working with rabies, veterinarians,
    animal and wildlife control workers, long-term travellers to endemic areas
  • eliminates need for HRIg following an exposure, and reduces number of HDCV PEP shots
    from 4 to 2

Systemic Infections

Sepsis and Septic Shock
• see Respirology, R33

Definitions
• systemic inflammatory response syndrome (SIRS): 2 or more of
  1. temperature <36°C/96.8°F or >38°C/100.4°F
  2. heart rate >90 beats/min
  3. respiratory rate >20 breaths/min or PaCO₂ <32 mmHg
  4. WBC <4 x 10⁹/L or >12 x 10⁹/L or >10% bands
• severe sepsis: SIRS + signs of end-organ dysfunction and hypoperfusion
• septic shock: severe sepsis + hypotension (<90 mmHg sBP), despite adequate fluid resuscitation

Pathophysiology
• causative agents are identified in only 50-70% of cases
• when organisms are identified, GP and GN organisms are the cause in 90% of cases
• primary bloodstream infection or secondary bacteremia → local immune response → immune
  cells release pro-inflammatory cytokines → immune response spreads beyond local environment
  → unregulated, exaggerated systemic immune response → vasodilation and hypotension →
  involvement of tissues remote from the site of injury/infection resulting in multiple major organ
dysfunction → periodic immunoparalysis
Clinical Features
- history: fever, chills, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
- physical: abnormal vitals (fever, tachypnea, tachycardia, hypotension), local signs of infection

Investigations
- CBC and differential, electrolytes, BUN, creatinine, liver enzymes, ABG, lactate, INR, PTT, FDP, blood C&S x2, urinalysis, urine C&S and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)

Treatment
- respiratory support: O₂ ± intubation
- cardiovascular support: IV fluids, ± norepinephrine + ICU
- IV antibiotics (empirical, depends on suspected source)
  - start with broad spectrum antibiotics (piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant GNS or vancomycin for MRSA)
  - narrow once susceptibilities are known
- hydrocortisone IV in patients with septic shock unresponsive to fluid resuscitation and vasopressors

Leprosy (Hansen’s Disease)

Etiology
- Mycobacterium leprae: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

Clinical Features
- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  i. paucibacillary “tuberculoid” leprosy (intact cell-mediated immune response)
     - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
     - early nerve involvement, enlarged peripheral nerves, neuropathic pain
     - may be self-limited, stable, or progress over time to multibacillary "lepromatous" form
  ii. multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
     - ≥6 lesions, symmetrical distribution
     - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
     - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  iii. borderline leprosy
     - lesions and progression lies between tuberculoid and lepromatous forms

Investigations
- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

Treatment (WHO Treatment Regimens)
- paucibacillary: dapsone + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampin, ofloxacin, and minocycline
- multibacillary and borderline: dapsone + rifampin monthly + clofazimine monthly x 12 mo
  AND low dose clofazimine once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

Prognosis
- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune reactions
Lyme Disease

Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (N. America), *B. garinii*, *B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- in Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment

Clinical Features
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, H/A, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) on thigh/groin/axilla
- stage 2 (early disseminated stage): weeks post-infection
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronicum atrophicans (due to *B. afzelii*)
  - neurologic: encephalopathy, meningitis, neuropathy

Investigations
- serology: ELISA, Western blot

Prevention
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- doxycycline prophylaxis within 72 h of removal of an engorged, *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks ≥20%) for patients >8 yr who are not pregnant or lactating

Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

Toxic Shock Syndrome

Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

Risk Factors
- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or Cesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

Clinical Features and Investigations
- acute onset
- Staphylococcal TSS
  - T >38.9°C
  - sBP <90 mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
• Streptococcal TSS
  ▪ sBP <90 mmHg
  ▪ isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  ▪ ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

Treatment
• supportive: fluid resuscitation
  ▪ Staphylococcal: for methicillin-susceptible S. aureus: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d
  ▪ Streptococcal: IV penicillin and clindamycin and ± IVIg

Cat Scratch Disease

Etiology
• Bartonella henselae: intracellular bacteria
• cat-to-human transmission via cat scratch/bite

Clinical Features
• skin lesion appears 3-10 d post-inoculation
• may be followed by fever, tender regional lymphadenopathy
• in some patients, organism may disseminate causing fever of unknown origin, hepatosplenomegaly, retinitis, encephalopathy
• usually self-limited

Investigations
• serology, PCR, lymph node biopsy

Treatment
• supportive in most cases
• azithromycin x 10-14 d with lymphadenitis in patients with moderate-severe disease or immunodeficiency

Rocky Mountain Spotted Fever

Etiology
• Rickettsia rickettsii: obligate intracellular GN organism
• reservoir hosts: rodents, dogs
• vectors: Dermacentor ticks
• organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
• can cause widespread vasculitis leading to H/A, and CNS changes; can progress to death if treatment is delayed

Clinical Features
• usually occurs in summer following tick bite
• influenza-like prodrome: acute onset fever, H/A, myalgia, N/V, anorexia
• macular rash appearing on day 2-4 of fever
  ▪ begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  ▪ occasionally “spotless” (10% of patients)

Investigations
• skin biopsy and serology (indirect fluorescent antibody test)

Treatment
• doxycycline, usually 5-7 d (treat for 3 d after defervescence)

West Nile Virus

Epidemiology
• virus has been detected throughout the United States and much of southern Canada
• overall case-fatality rates in severe cases are ~10%

Transmission
• primarily from mosquitoes that have fed on infected birds (crows, blue jays)
• transplacental, blood products (rare), organ transplantation
Clinical Features
- most are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of H/A, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoencephalitis, and acute flaccid paralysis (especially in those >60 yr)

Investigations
- IgM antibody in serum or CSF (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood, and fluids (all have low sensitivity)
- CSF: elevated lymphocytes and protein if CNS involvement

Treatment and Prevention
- treatment: supportive
- prevention: mosquito repellant (DEET), drain stagnant water, community mosquito control programs

Syphilis

Etiology
- Treponema pallidum: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

Clinical Features
- see Dermatology, D32 and Gynecology, GY30
- multi-stage disease
  1. primary syphilis (3-90 d post-infection)
     - painless chancre at inoculation site (any mucosal surface)
     - regional lymphadenopathy
     - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
  2. secondary syphilis = systemic infection (2-8 wk following chancre)
     - maculo-papular non-pruritic rash including palms and soles
     - generalized lymphadenopathy, low grade fever, malaise, H/A, aseptic meningitis, ocular/otic syphilis
     - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
  3. latent syphilis
     - asymptomatic infection that follows untreated primary/secondary syphilis
     - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
     - increased transmission risk with early latent; longer treatment duration required for late latent
  4. tertiary syphilis (1-30 yr post-infection)
     - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
     - aortic aneurysm and aortic insufficiency
     - neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis
  5. congenital syphilis
     - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
     - most infected newborns are asymptomatic
     - clinical manifestation in early infancy include rhinitis (sniffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis)
     - late onset manifestations (>2 yr of age) include saddle nose, saber shins, joint deformities, Hutchinson’s teeth, mulberry molars, ragades, CN VIII deafness, interstitial keratitis, juvenile paresis

Investigations
- screening tests: CMIA, CLIA, EIA (treponemal), RPR, or VDRL (non-treponemal)
- confirmatory tests: TPPA, FTA-ABS, MHA-TP, TPI, dark field microscopy with silver stain (rarely)
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others
- for congenital syphilis, LP is essential; long bone x-rays may also be helpful

Treatment
- for 1st, 2nd, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3rd, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if allergic to penicillin: doxycycline 100 mg PO bid x 14 d
- neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d
- for congenital syphilis, penicillin G IV x 10 d
- see Family Medicine, FM45 for generalized STI workup
Tuberculosis

Etiology, Epidemiology, and Natural History

- 1/3 of the world’s population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 95% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 2-3 yr of initial infection) at a pulmonary or extrapulmonary site

Figure 8. Tuberculosis statistics

Canadian Tuberculosis Standards, 7th ed.

Risk Factors

- social and environmental factors
  - travel or birth in a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - Aboriginal (particularly Inuit), crowded living conditions, low SES/homeless, IVDU
  - personal or occupational contact
- host factors
  - immunocompromised/immunosuppressed (especially HIV, including extremes of age)
  - silicosis
  - chronic renal failure requiring dialysis
  - malignancy and chemotherapy
  - substance abuse (e.g. drug use, alcoholism, smoking)

Clinical Features

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
  1. pulmonary TB
    - chronic productive cough ± hemoptysis
    - CXR consolidation or cavitation, lymphadenopathy
    - non-resolving pneumonia despite standard antimicrobial therapy
  2. miliary TB
    - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
    - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung
  3. extrapulmonary TB
    - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott’s disease), adrenal (causing Addison’s disease), renal, ovarian

Tuberculous Polyserositis
pleural + pericardial + peritoneal effusions (usually from granuloma breakdown that spills TB into pleural cavity – very rare)
**Investigations**
- screening for latent TB
  - PPD/Mantoux skin tests
    - both tests diagnose prior TB exposure; neither can diagnose or exclude active disease
  - IFN-γ release assay (IGRA)
    - in patients previously infected with TB, T-cells produce increased amounts of IFN-γ when re-exposed to TB antigen
    - detects antigen not present in the BCG vaccine or in most types of non-tuberculous-mycobacteria (NTM), therefore fewer false positives
- Canadian and American guidelines treat IGRA as equivalent to the TB skin test and preferable in patients with a history of BCG vaccination or who may not return for a skin test reading
- diagnostic tests/investigations for active pulmonary TB
  - three sputum specimens (either spontaneous or induced) should be collected for acid-fast bacilli smear and culture; the three specimens can be collected on the same day, a minimum of 1 hour apart
  - BAL
  - CXR
    - nodular or alveolar infiltrates with cavitation (middle/lower lobe if primary, apical if secondary)
    - pleural effusion (usually unilateral and exudative) may occur independently of other radiograph abnormalities
    - hilar/mediastinal adenopathy (especially in children)
    - tuberculoma (semi-calcified well-defined solitary coin lesion 0.5-4 cm that may be mistaken for lung CA)
    - miliary TB
    - evidence of past disease: calcified hilar and mediastinal nodes, calcified pulmonary focus, pleural thickening with calcification, apical scarring

**Prevention**
- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against pediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection or immunodeficiency; widely used in other countries
- secondary prevention (defer in pregnancy unless mother is high risk)
  - likely INH-sensitive: isoniazid (INH) + pyridoxine (vit B6 to help prevent INH-associated neuropathy) x 9 mo
  - likely INH-resistant: rifampin x 4 mo

**Treatment of Active Infection**
- empiric therapy: INH + rifampin + pyrazinamide + ethambutol + pyridoxine
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol + pyridoxine x 2 mo (initiation phase), then INH + rifampin + pyridoxine x 4 mo in fully susceptible TB (continuation phase), total 6 mo
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin ± others
  - XDR = resistance to INH + rifampin + fluoroquinolone + ≥1 of injectable, second-line agents
  - very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
  - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information: www.phac-aspc.gc.ca/tbpc-latb/pubs/tb-canada-7/index-eng.php)
HIV and AIDS

Epidemiology

Canadian Situation (Public Health Agency of Canada, 2013)
- estimated 71,300 Canadians living with HIV infection at the end of 2011, 25% unaware of HIV-positive status
- 2,090 new infections were reported in 2013: MSM account for 49.3% of cases, IVDU 12.8%

Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2014)
- estimated 35 million people living with HIV/AIDS in 2013
- estimated 2.1 million newly infected in 2013
- estimated 1.5 million AIDS-related deaths in 2013

Definition and Pathophysiology

- HIV is a retrovirus that causes progressive immune system dysfunction which predisposes patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17) and capsid (p24) enclosing 2 single-stranded copies of RNA + enzymes in its core
- virion glycoproteins bind CD4 and CXCR4/CCR5 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by reverse transcriptase; dsDNA is integrated into host genome
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover

Modes of Transmission

Adapted with permission from Macmillan Publishers Ltd. Nat Rev Immunology 2008;8:447-457

NOTE: these estimates are for “all comers” i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)
Natural History

Figure 10. Relationships between CD4 T-cell count, viral load, and anti-HIV antibodies

Acute (Infection) Retroviral Syndrome
- 40-90% experience an acute "flu-like" illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, H/A, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high risk of transmission

Asymptomatic (Latent) Stage
- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count: 500-1,100 cells/mm³
- CD4 count drops 60-100 cells/mm³ per year
- by 10 yr post-infection, 50% have AIDS, 30% demonstrate milder symptoms, and <20% are asymptomatic if left untreated

AIDS Definition in Canada
- HIV-positive AND
- one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. PJP (previously PCP), esophageal candidiasis, CMV, MAC, TB, toxoplasmosis), malignancy (Kaposi’s sarcoma, invasive cervical cancer), wasting syndrome OR
- CD4 <200 (or <15%); this is largely historical since ART can reverse CD4 count decline

Table 21. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)

<table>
<thead>
<tr>

<th>Possible Manifestations</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;500 cells/mm³</td>
<td>Often asymptomatic. Constitutional symptoms: fever, night sweats, fatigue, weight loss Mucocutaneous lesions: seborrheic dermatitis, HSV, VZV (shingles), oral hairy leukoplakia (EBV), candidiasis (oral, esophageal, vaginal), Kaposi’s sarcoma (KS) Recurrent bacterial infections, especially pneumonia Pulmonary and extrapulmonary tuberculosis Lymphoma</td>
</tr>
<tr>
<td>&lt;200 cells/mm³</td>
<td>Pneumocystis jiroveci pneumonia (formerly PCP) KS Oral thrush Local and/or disseminated fungal infections: Cryptococcus neoformans, Coccidioides immitis, Histoplasma capsulatum</td>
</tr>
<tr>
<td>&lt;100 cells/mm³</td>
<td>Progressive multifocal leukoencephalopathy (PML) – JC virus CNS toxoplasmosis</td>
</tr>
<tr>
<td>&lt;50 cells/mm³</td>
<td>CMV infection: retinitis, colitis, cholangiopathy, CNS disease Mycobacterium avium complex (MAC) Bacillary angiomatosis (disseminated Bartonella) Primary central nervous system lymphoma (PCNSL)</td>
</tr>
</tbody>
</table>

Laboratory Diagnosis
- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): enzyme linked immunosorbent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
Management of the HIV-Positive Patient

• verify positive HIV test
• complete baseline history and physical exam, then follow-up every 3-6 mo
• laboratory evaluation
  • routine CD4 count to measure status of the immune system
  • also important indicator of effect of ART
  • baseline HIV resistance testing to guide ARV therapy
• HLA-B*5701 genetic test to screen for abacavir hypersensitivity
• baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
• baseline serologies (hepatitis A, B, and C, syphilis, toxoplasma, CMV, VZV)
• routine biochemistry and hematology, CXR
• annual fasting lipid profile and fasting glucose (due to HAART side effects)
• education
  • regular follow-up on CD4 counts and viral loads (q3-6mo) as well as strict adherence to ART improves prognosis
  • prevention of further transmission through safer sex and clean needles for injection drug use
  • HIV superinfection (transmission of different HIV strains from another HIV+ person) does rarely occur so barrier protection during sex is still recommended
• discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
• connect to relevant community groups and resources
• health care maintenance
  • assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  • vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative)
  • annual screening (PAP smear, STIs)
• management of comorbid conditions and provision of general primary care

SS = single strength; DS = double strength

Anti-Retroviral Treatment

Overall Treatment Principles
• recommended that all HIV+ patients initiate HAART to prevent disease progression and transmission; strength of evidence supporting this recommendation changes depending on CD4 count and sexual practices (AI evidence that CD4 350 should be on HAART)
• patients starting HAART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case by case basis
• initiate ART if opportunistic infection/malignancy, pregnancy, HIV-associated nephropathy, HIV-associated thrombocytopenia, need for hepatitis B therapy in HBV co-infected patients
• consider starting treatment early if HCV co-infection, high HIV viral load, comorbid conditions (e.g. cardiovascular disease)
• consider results of baseline resistance testing and complete ART history before (re-)initiating HAART
• goal: keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunologic function
• strong evidence against intermittent HAART or ‘drug holidays’
• ART leads to 96% reduction in risk of transmitting HIV to sexual partners

Viral load: rate of progression
• CD4 count: progress and stage of disease

HIV Status
• 1° and 2° prophylaxis may be discontinued if CD4 count is above threshold for ≥6 mo while on ART

HLA-B*5701 Testing
Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of Caucasians, lower prevalence in other ethnic groups). Routine screening for HLA-B*5701 at baseline and definitely prior to abacavir use

Reasons for Deterioration of a Patient with HIV/AIDS
• Opportunistic infections
• Neoplasms
• Medication-related toxicities
• Co-infections (e.g. HBV, HCV, STIs)
• Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)
HAART Recommendations for Treatment of Naïve Patients

- 2 NRTIs + 1 INSTI/NNRTI/PI (boosted with ritonavir or cobicistat)

Treatment Failure

- defined clinically (HIV progression), immunologically (failure to increase CD4 count by 25-50 over first yr of treatment or CD4 decrease >100 over 1 yr), or virologically (failure to achieve viral load <40 copies/mL after 6 mo)
- ensure that viral load >40 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, perform resistance testing

Prevention of HIV Infection

- education, including harm-reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for injection drug users: avoid sharing needles
- treatment of HIV+ women with HAART during the 2nd and 3rd trimester of pregnancy and AZT during delivery followed by treatment of the infant for 6 wk (decreases maternal-fetal transmission from 25% to <3%)
- universal blood and body precautions for health care workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV although additional data needed
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation
**Types of Testing**

1. **Nominal/Name-Based HIV Testing**
   - person ordering the test knows the identity of the person being tested for HIV
   - HIV test is ordered using the name of the person being tested
   - person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
   - test result is recorded in the health care record of the person being tested

2. **Non-Nominal/Non-Identifying HIV Testing**
   - similar to nominal/name-based testing on all points except:
     - HIV test is ordered using a code or the initials of the person being tested

3. **Anonymous Testing**
   - available at specialized clinics
   - person ordering the HIV test does not know the identity of the person being tested
   - HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
   - test results are not recorded on the health care record of the person being tested
   - patient identification and notification of Public Health required to gain access to ART

**HIV Pre- and Post-Test Counselling**

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

**Fungal Infections**

**Skin and Subcutaneous Infections**

**Superficial Fungal Infections**
- see **Dermatology, D27**

**Dermatophytes**
- see **Dermatology, D27**

**Subcutaneous Fungal Infection**

**Pathophysiology**
- fungi that naturally reside in soil and enter skin via traumatic break
  - *Sporothrix schenckii*: most commonly affects gardeners injured by a rose thorn or splinter
    - causes subcutaneous nodule at point of entry
    - fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

**Treatment**
- oral azole (e.g. itraconazole)
- IV amphotericin B for severe or disseminated infection

**Endemic Mycoses**

**Basics**
- three major endemic mycoses in North America
  - histoplasmosis
  - blastomycosis
  - coccidioidomycosis

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts, and bat caves
• thermally dimorphic organisms: mold in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
• infection occurs through inhalation of spores (soil, bird droppings, vegetation) or inoculation injury
• all can cause pneumonia and may disseminate hematogenously
• may reactivate or disseminate during immunocompromised states

Treatment
• common to all endemic mycoses
  • oral azole (e.g. itraconazole for mild-moderate local infection)
  • IV amphotericin B for systemic infection

Table 25. Endemic Mycoses

<td>Sputum culture Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material)</td>
</tr>
</tbody>
</table>

Opportunistic Fungi

Pneumocystis jiroveci (formerly P. carinii)
Pneumonia: PJP or PCP

Microbiology
• unicellular fungi
• previously classified as a protozoa

Transmission
• rarely person-to-person transmission
• most disease is due to reactivation of latent infection acquired by the respiratory route or reinfestation by a different genotype
  • causes clinical disease in immunocompromised patients (steroid use, HIV)
  • 80% lifetime risk without prophylaxis (TMP/SMX) in HIV patients with CD4 count <200 cells/mm³

Clinical Features
• symptoms of pneumonia: fever, nonproductive cough, progressive dyspnea
• classic CXR

Investigations
• demonstration of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)
Treatment and Prevention
• oxygen to keep SaO₂ >90%
• antimicrobial options
  ▪ TMP/SMX (PO or IV)
  ▪ dapsone and TMP
  ▪ clindamycin and primaquine
  ▪ pentamidine (IV)
  ▪ atovaquone
• corticosteroids used as adjuvant therapy in those with severe hypoxia (pO₂ <70 mmHg or A-a gradient O₂ >35 mmHg)
• prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 <200 cells/mm³ or non-HIV immunocompromised patients under specific conditions)

**Cryptococcus spp.**

Microbiology
• encapsulated yeast found worldwide
• 2 human pathogenic species: *C. gattii*, *C. neoformans*

Transmission
• inhalation of airborne yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gattii*) → may cause local infection in lung → asymptomatic or pneumonia
• may also spread hematogenously to the CNS, skin, bones, and other organs
• *C. neoformans* tends to affect immunocompromised hosts
• *C. gattii* tends to affect immunocompetent hosts

Clinical Features
• pulmonary
  ▪ usually asymptomatic or self-limited pneumonia
  ▪ only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
• disseminated
  ▪ frequently disseminates in HIV+ population
  ▪ CNS: meningitis (leading cause of meningitis in patients with HIV)
  ▪ skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*

Investigations
• serum cryptococcal antigen
• CSF for meningitis: India-ink stain, cryptococcal antigen test, culture to confirm

Treatment
• in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  ▪ amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  ▪ switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

**Candida albicans**

Microbiology
• yeast forms with pseudohyphae germ tube formation at 37°C

Transmission
• normal flora of skin, mouth, vagina, and GI tract
• risk factors for overgrowth:
  ▪ immunocompromised state (DM, corticosteroids)
  ▪ ICU patients (broad-spectrum antibiotic use, central venous catheters, TPN)
  ▪ obesity → maceration and moisture in intertriginous areas, pannus, under breasts

Clinical Features
• mucocutaneous
  ▪ oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see Gynecology, GY27), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  ▪ small satellite lesions beyond the margin of the rash
• invasive
  ▪ candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease
Treatment
- thrush: nystatin suspension or pastilles for mild disease, fluconazole for severe disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

Aspergillus spp.

Microbiology
- branching septate hyphae
- common species causing disease include A. fumigatus, A. fla

Transmission
- ubiquitous in the air and the environment
- Aspergillus produces a toxin called aflatoxin that contaminates nuts, grains, and rice

Clinical Features
- allergic bronchopulmonary aspergillosis (ABPA)
- IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
- occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
- ball of hyphae in a preexisting lung cavity
- symptoms range from asymptomatic to massive hemoptyis
- CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes (“air crescent” sign)
- invasive aspergillosis
- associated with prolonged and persistent neutropenia or transplantation
- pneumonia – most common
- may disseminate to other organs: brain, skin
- severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
- CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass (“halo” sign)
- mycotoxicosis
- aflatoxin produced by A. flavus (nuts, grains, rice)
- results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

Treatment Options
- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for ABPA

Parasitic Infections

Protozoa – Intestinal/Genitourinal Infections

Entamoeba histolytica (Amoebas)

Transmission
- reservoir: infected humans
- cysts by fecal-oral and food/waterborne transmission in areas of poor sanitation
- seen in immigrants, travellers, institutionalized individuals, Aboriginal Canadians, MSM

Clinical Features
1. asymptomatic carriers
2. amoebic dysentery
   - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea
   secondary to local tissue destruction and ulceration of large intestine
3. amoebic abscesses
   - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
   - can also occur in lungs and brain

Figure 12. Entamoeba life cycle
Investigations
- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- *E. histolytica* indistinguishable microscopically from the non-pathogen *E. dispar* (distinguish by specific stool antigen detection)

Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

### Giardia lamblia

**Transmission**
- reservoir: infected humans and other mammals
- food/waterborne (especially in the Rockies) and fecal-oral transmission of infectious cysts
- risk factors: travel, camping, institutions, day care centres, MSM

**Clinical Features**
- giardiasis (“beaver fever”)
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucous in stool

**Investigations**
- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

**Treatment and Prevention**
- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

### Trichomonas vaginalis

**Transmission**
- sexual contact

**Clinical Features**
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- *trichomonas vaginalis* (see Gynecology, GY27)
  - vaginal discharge (profuse, malodourous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

**Investigations**
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

**Treatment**
- metronidazole for patient and partner(s)

### Cryptosporidium spp.

**Transmission**
- reservoir: infected humans and a wide variety of young animals
- fecal-oral transmission by ingestion of cysts; waterborne
- risk factors: summer and fall, young children (day care), MSM, contact with farm animals, immunodeficiency

**Clinical Features**
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with N/V, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)
Investigations
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

Treatment and Prevention
- supportive care
- in HIV, try HAART to restore immunity; if fails, try nitazoxanide
- good personal hygiene, water filtration

Blood and Tissue Infections

Plasmodium spp. (Malaria)

Microbiology
- species include: P. falciparum (most common and most lethal), P. vivax, P. ovale, P. malariae, P. knowlesi (new species isolated from primates in Malaysia, potentially fatal)
- complex life cycle: human host for asexual reproduction and mosquito for sexual reproduction
- sporozoites from mosquitoes infect human liver cells, where they multiply and are released as merozoites; merozoites infect RBCs and cause disease
- P. ovale and P. vivax can produce dormant hypnozoites in the liver that may cause relapsing malarial attacks by reactivating (entering the erythrocytic cycle) after many months

Transmission
- reservoir: infected human
- transmission by the night-biting female Anopheles mosquito, vertical transmission, and blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Features
- flu-like prodrome
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs) (lasts several hours)
  - P. vivax and P. ovale: chills and fever x48h but can be variable
  - P. malariae: chills and fever x72h but can be variable
  - P. falciparum: less predictable fever interval, can be highly variable (>90% ill within 30 d)
- abdominal pain, diarrhea, myalgia, H/A, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis

Complications
- P. falciparum: CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
- P. knowlesi, and rarely P. vivax, can be fatal

Investigations
- microscopy: blood smear q12-24h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
  - rapid antigen detection tests

Treatment and Prevention
- P. vivax, P. ovale: chloroquine (and primaquine to eradicate liver forms)
- P. vivax, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- P. malariae, P. knowlesi: chloroquine
- P. falciparum: most areas of the world show chloroquine resistance – check local resistance patterns
  - artemisinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - atovaquone/proguanil combination (Malarone®)
  - quinine + doxycycline or clindamycin
  - mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- prevention with antimalarial prophylaxis, covering exposed skin, net insect repellent

Malaria is the most common fatal infectious disease worldwide

Figure 13. Life cycle of Plasmodium spp.

Drugs for Preventing Malaria in Travellers
Cochrane Database Syst Rev 2008;CD006491
Study: Cochrane Systematic Review. 8 RCTs.
Population: 4,240 non-immune adults and children traveling to regions with P. falciparum resistance to chloroquine.
Intervention: Atovaquone-proguanil, doxycycline, mefloquine, chloroquine-proguanil, or primaquine used for malaria prophylaxis.
Outcome: Efficacy, safety, and tolerability.
Results: Atovaquone-proguanil and doxycycline had similar adverse events. Atovaquone-proguanil had fewer overall (RR 0.72), GI (RR 0.54), and neuropsychiatric events (RR 0.48) than mefloquine. Dapsone also had fewer neuropsychiatric events than mefloquine (RR 0.84).
Conclusion: Atovaquone-proguanil or doxycycline as prophylaxis against malaria is best tolerated in terms of adverse effects and mefloquine is associated with adverse neuropsychiatric outcomes.
**Trypanosoma cruzi**

**Transmission**
- found in Mexico, South America, and Central America
- transmission by Reduviid insect vector ("Kissing Bug"), which defecates on skin and trypanomastigotes in the stool are rubbed into bite site by host
- also transmitted via placental transfer, organ donation, blood transfusion, and ingestion of contaminated food containing Reduviid insects (especially cane juice)

**Clinical Features**
- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation ("Romana’s sign"; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood; most infected persons (60-70%) remain in this phase, and do not go on to manifest a determine form of Chagas disease
  - chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

**Investigations**
- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

**Treatment and Prevention**
- acute: nifurtimox or benznidazole
- indeterminate: increasing trend to treat as acute infection
- chronic determinate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there may be a benefit to antiparasitic treatment
- insect control, bed nets

---

**Toxoplasma gondii**

**Transmission**
- acquired through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions

**Clinical Features**
- congenital
  - result of acute primary infection of mother during pregnancy (TORCH infection – see Obstetrics, OB31)
  - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult → blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
  - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 <200)
  - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (H/A and focal neurological signs)
  - lymph node, liver, and spleen enlargement and pneumonitis
  - chorioretinitis

**Investigations**
- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination
- negative serology in many AIDS patients (false negative due to decreased lymphocyte population)

**Treatment and Prevention**
- no treatment if: immunocompetent, not pregnant, no severe organ damage
- pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folic acid), avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: pyrimethamine + sulfadiazine (see Prophylaxis, ID31)
- eye disease, meningitis: corticosteroids
- proper hand hygiene, cook meat thoroughly to proper temperature

---

**1/3 of Ontario’s population is infected with Toxoplasma gondii**

</table>

#### Schistosoma spp.

**Species**
- *S. mansoni*, *S. hematobium*, *S. japonicum*

**Transmission**
- larvae ( cercariae), released from snails, penetrate unbroken skin in infested fresh water
- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- eggs must reach fresh water to hatch; schistosomes cannot multiply in or pass between humans
  - more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

**Clinical Features**
- most asymptomatic; symptoms seen in travellers (nonimmune)
- swimmer’s itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, H/A, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia

**Complications of Chronic Infection**
- *S. mansoni*, *S. japonicum*
  - worms in mesenteric vein, eggs in portal tracts of liver and bowel
  - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegalay (2° to portal HTN), hepatomegaly
- *S. hematobium*
  - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
  - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
  - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
  - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

**Figure 17. Life cycle of Schistosoma**
Ectoparasites

- scabies, lice
- see Dermatology, D28

Travel Medicine

General Travel Precautions
- vector-borne: long sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings, and bed nets, and skin repellents (such as DEET) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rains
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller’s diarrhea (bismuth salicylate)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

Infectious Diseases to Consider
- vector borne: malaria, dengue fever, Chikungunya fever, yellow fever, spotted fever rickettsioses, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, leishmaniasis
- sexually transmitted: HIV, HBV, acute HSV, syphilis, usual STIs
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis
- orally transmitted: HBV, HEV, acute HSV, typhoid fever, paratyphoid, amoebiasis, dysentery
- airborne: TB
- food/water: HAV, HEV, Brucella, Salmonella, Shigella, Giardia, listeria, cryptosporidium, cyclospora
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

Fever in the Returned Traveller

Etiology
- commonly identified causes of fever in returning traveller
  - parasitic: malaria (20-30%)
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from *Salmonella* (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller’s diarrhea (10-20%), RTI (10-15%), UTI/STI (2-3%)
- febrile illness in travellers can be caused by routine infections that are common in nontravellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes (e.g. DVT, PE)

History
- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
• persons visiting friends and family more likely to be exposed to local population and pathogens
  ▪ style of travel: lodgings, camping, adventure travelling
  ▪ local population: sick contacts
  ▪ transportation: use of animals

• exposure history
  ▪ street foods, untreated water: increased risk of traveller’s diarrhea, enteric fever
  ▪ uncooked meat unpasteurized dairy: increased risk of parasitic infection
  ▪ body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  ▪ increased risk of HBV, HCV, HIV, GC, C. trachomatis, syphilis
  ▪ animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies

• fever pattern
• incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  ▪ <21 d: consider malaria, typhoid fever, dengue fever, rickettsioses; exclude HBV, TB
  ▪ >21 d: consider malaria, TB; exclude dengue fever, traveller’s diarrhea, rickettsioses

• body systems affected: GI, respiratory, CNS, skin

Investigations
• all travellers with fever should undergo the following tests
  ▪ blood work: CBC and differential, liver enzymes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  ▪ urine: urinalysis, urine C&S if dysuria or other localizing signs
• special tests based on symptoms, exposure history, and geography
  ▪ stool: C&S, O&P
  ▪ CXR
  ▪ dengue serology for IgM

</tbody>
</table>

**Etiology of Classic FUO**
- Infectious causes (~30%)
  - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - Abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
  - Osteomyelitis
  - Bacterial endocarditis (culture negative)
  - Uncommon: viral (CMV, EBV), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- Neoplastic causes (~20%)
  - Most commonly lymphomas (especially non-Hodgkin’s) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - Solid tumours: RCC (most common), also breast, liver ( hepatoma), colon, pancreas, or liver metastases
- Collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still’s disease
- Miscellaneous (~20%)
  - Drugs, factitious fever
  - Sarcoidosis, granulomatous hepatitis, IBD
  - Hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - Venous thromboembolic disease: PE, DVT
  - Endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- Unknown in 30-50% despite detailed workup

**Approach to Classic FUO**
- Careful history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- Thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- Initial investigations as appropriate
  - Blood work: CBC and differential, electrolytes, BUN, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
  - Cultures: blood (x2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
  - Serology: HIV, monospot, CMV IgM
  - Imaging: CXR, abdominal imaging
- If there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- If no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - Without intervention: patients that remain undiagnosed despite extensive workup have good prognosis

**Causes of Nosocomial FUO**
- B, C, D, E
  - Bacterial and fungal infections of respiratory tract and surgical sites
  - Catheters (intravascular and urinary)
  - Drugs
  - Emboli

**Drugs that may Cause Fever**
- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimalarials)
- Anti-hypertensives (hydralazine, methyldopa)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arythmics (quinine, procainamide)
- Anti-inflammatory (NSAIDs)
- Anti-thrombotics (ASA)
- Anti-histamines
- Anti-thyroid
Infections in the Immunocompromised Host

- Immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent
- Type of immunodeficiency predicts probable spectrum of agents

Factors that Compromise the Immune System
- General: age (very young or elderly), malnutrition
- Immune disease: HIV/AIDS, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- Iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

Table 30. Types of Immunodeficiency

<table>
<thead>
<tr>
<th>Type</th>
<th>Conditions</th>
<th>Vulnerable To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell-Mediated Immunity</td>
<td>HIV, Hodgkin’s, hairy cell leukemia, cytotoxic drugs, SCID, DiGeorge syndrome</td>
<td>Latent viruses, Fungi, Parasites</td>
</tr>
<tr>
<td>Humoral Immunity</td>
<td>CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome</td>
<td>Encapsulated organisms (S. pneumoniae, H. influenzae, N. meningitidis, Salmonella typhi, GBS)</td>
</tr>
<tr>
<td>Neutrophil Function</td>
<td>Myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease</td>
<td>Catalase-producing organisms (Staphylococcus, Serratia, Nocardia, Aspergillus)</td>
</tr>
</tbody>
</table>

Febrile Neutropenia

Definition
- Fever (≥38.3°C/101°F or ≥38.0°C/100.4°F for ≥1 h) and one of
  - ANC <0.5 OR
  - ANC <1.0 but trending down to 0.5

Pathophysiology
- Decreased neutrophil production
  - Marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - Iatrogenic: cancer chemotherapy, radiation, drugs
  - Deficiencies: vitamin B12, folate
- Increased peripheral neutrophil destruction
  - Autoimmune: Felty’s syndrome, SLE, antineutrophil antibodies
  - Splenic sequestration

Epidemiology/Etiology
- Most common life-threatening complication of cancer therapy
- 8 cases per 1,000 cancer patients per yr in the U.S.
- Causative organism identified only 1/3 of the time
- GN (especially Pseudomonas) historically most common
- GP more common now
- Fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially Candida, Aspergillus)

Investigations
- Examine for potential sites of infection: mucositis and line infections are most common
- Do NOT perform DRE; examine perianal region
- Blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and NP swab for respiratory viruses
- CBC and differential, Cr, BUN, electrolytes, AST/ALT, total bilirubin

Treatment
- Most hospitals have their own specific protocol; one example is presented below

ANC (absolute neutrophil count) = WBC x (%neutrophils + %bands)

Usual signs and symptoms of infection may be diminished because neutrophils are required for a robust inflammatory response; exam and x-ray findings may be more subtle.

WBC is lowest between 5-10 d after last chemotherapy cycle

Prophylaxis against FN with G-CSF (granulocyte colony-stimulating factor) and GM-CSF (granulocyte-macrophage colony-stimulating factor) decreases hospitalization without affecting mortality (indicated if risk of FN 20% or if FN has occurred in a previous chemotherapy cycle)
Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
  - viral (especially CMV, EBV, VZV)
  - fungal (especially Aspergillus, Cryptococcus, P. jiroveci)
  - protozoan (especially Toxoplasma)
  - unusual bacterial/mycobacterial infections (especially TB, Nocardia, Listeria)

Prophylactic Vaccinations Given Before Transplant
- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B vaccines
- if low titre or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

Immune Reconstitution Syndrome

Definition
- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

Etiology
- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in HIV/AIDS or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- can occur in response to multiple infections
  - Mycobacteria (tuberculosis, avium complex)
  - Cryptococcus
  - Pneumocystis
  - Toxoplasma
  - HBV and HCV
  - Herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
**A Simplified Look at Antibiotics**

- general overview, see Table 31 for more details

1. Penicillins

   ![Penicillin G (IV)/Penicillin V (PO)
   (most Streptococci, N. meningitidis, many oral anaerobes except B. fragilis)
   Ampicillin (IV)/Amoxicillin (PO)
   + Enterococcus and H. influenzae, Proteus, Listeria, E. coli, Salmonella, Shigella
   Amoxicillin-clavulanate
   + β-lactamase producing organisms including anaerobes
   Piperacillin
   + Pseudomonas and Enterobacter
   Piperacillin/tazobactam
   + β-lactamase producing organisms including anaerobes
   Cloxacillin
   + MSSA but 4 Streptococci

   **Figure 19. Penicillins**

2. Cephalosporins (PO/IV)
   - 1st generation: cephalexin/cefazolin (mostly GP, some GN)
   - 2nd generation: cefuroxime/cefprozil (some GP and some GN, *anaerobes)
   - 3rd generation: cefixime/cefotaxime, ceftriaxone (good Streptococcal coverage, mostly GN), and cefazidime (no GP, mostly GN, *Pseudomonas*)
   - 4th generation: --/cefepime (most GP, most GN, *Pseudomonas*)

3. Aminoglycosides (GN aerobic bacilli)
   - gentamicin
   - tobramycin
   - amikacin

   - erythromycin
   - clarithromycin
   - azithromycin

5. Fluoroquinolones (GN – although resistance becoming a huge problem)
   - ciprofloxacin (+ *Pseudomonas*)
   - norfloxacin (for UTI only)
   - respiratory fluoroquinolones (some GP, GN, "atypicals", *Legionella, Mycoplasma, Chlamydia phila, Mycobacteria*)
   - levofloxacin
   - moxifloxacin (+ anaerobes)
6. Carbapenems (broad coverage: GP, GN, and anaerobes)
- imipenem (+ Pseudomonas)
- meropenem (+ Pseudomonas)
- ertapenem

7. Others
- doxycycline/tetracycline (GP, syphilis, Chlamydia phila, Rickettsia, Mycoplasma)
- tigecycline (for resistant GP infections, GN, anaerobes, Chlamydia phila, Rickettsia, Mycoplasma)
- vancomycin (all GP and C. difficile – the oral form)
- linezolid (for resistant GP infections)
- daptomycin (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most S. aureus including: MRSA, GN aerobes, Pneumocystis)
- nitrofurantoin (GN bacilli, S. saprophyticus, Enterococcus)
- linezolid (for resistant GP infections)
- daptomycin (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most S. aureus including: MRSA, GN aerobes, Pneumocystis)
- nitrofurantoin (GN bacilli, S. saprophyticus, Enterococcus)
- vancomycin (all GP and C. difficile – the oral form)
- linezolid (for resistant GP infections)
- treatment for C. difficile: metronidazole OR oral vancomycin; consider both in serious infection

**Antimicrobials**

**Antibiotics**

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S
    - if causative organism identified, use antibiotic to which organism is sensitive
    - if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

**Reasons for Combination Therapy**
- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. Enterococcus spp. causing endocarditis)
- To prevent emergence of resistance

---

**Figure 20. Mechanism of action of antibiotics**

Imaging Modalities

X-Ray Imaging
- X-rays, or Röentgen rays, are a form of electromagnetic energy of short wavelength
- As x-ray photons traverse matter, they can be absorbed (a process known as “attenuation”) and/or scattered
- The density of a structure determines its ability to attenuate or “weaken” the x-ray beam
  - Air < fat < water < bone < metal
- Structures that have high attenuation (e.g. bone) appear white on the resulting images

Plain Films
- X-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- Structures closer to the film appear sharper and less magnified
- Contraindications: pregnancy (relative)
- Advantages: inexpensive, non-invasive, readily available, reproducible, fast
- Disadvantages: radiation exposure, generally poor at distinguishing soft tissues

Fluoroscopy
- Continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- On the fluoroscopic image, black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear light
- Advantages: allows for real-time visualization of structures
- Disadvantages: increased radiation dose; however, the use of pulsed fluoroscopy has reduced fluoroscopy time by 76% and radiation dose by 64% as compared with continuous fluoroscopy

Computed Tomography
- X-ray beam opposite a detector moves in a continuous 360° arc as patient is advanced through the imaging system
- Subsequent computer assisted reconstruction of anatomical structures from the axial plane
- Attenuation is quantified in Hounsfield units:
  - Subsequent computer assisted reconstruction of anatomical structures from the axial plane
  - Adjusting the “window width” (range of Hounsfield units displayed) and “window level” (midpoint value of the window width) can maximize visualization of certain anatomical structures (e.g. CT chest can be viewed using “lung”, “soft tissue”, and “bone” settings)
- Contraindications: pregnancy (relative), contraindications to contrast agents (e.g. allergy, renal failure)
- Advantages: delineates surrounding soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, spiral/helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA is less invasive than conventional angiography
- Disadvantages: high radiation exposure, soft tissue characterization is not as good in comparison with MRI, IV contrast injection, anxiety of patient when going through scanner, higher cost, and less available than plain film

Ultrasound
- High frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
  - Reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
  - Structures are described based on their echogenicity: hyperechoic structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves not reflected back but pass through)
  - Higher U/S frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
  - Artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. tissue/bone) or absorbs (e.g. tissue/bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
  - Duplex scan: grey-scale image that utilizes the Doppler effect to visualize the velocity of blood flow past the transducer
  - Colour Doppler: assigns a color based on the direction of blood flow
  - Advantages: relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), determines cystic versus solid
  - Disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation

Attenuation
- Bone (= bright) > grey matter > white matter (“fatty” myelin) > CSF > air (= dark)

Typical Effective Doses from Diagnostic Medical Examinations (in adults)*

**Calculated using average natural background exposure in Canada (Health Canada: http://www.hc-sc.gc.ca/hsf/rx/yh-uv/env/environ/espas-eng.php)
Magnetic Resonance Imaging

- non-invasive technique that does not use ionizing radiation
- able to produce images in virtually any plane
- patient is placed in a magnetic field; protons (H\(^+\)) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on which deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by a computer to generate MR images
- the MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Positron Emission Tomography Scans

- non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- nuclear medicine imaging technique that produces images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotope, such as \(^{18}\)FDG is chemically incorporated into a metabolically active molecule (e.g. glucose), injected into patient, which travels to target organ, accumulates in tissues of interest, and as radioactive substance begins to decay, gamma rays are produced which are detected by PET scanner
- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic), in oncology allows diagnosis, staging, restaging, has predictive and prognostic value, can evaluate cardiac viability
- disadvantages: cost, ionizing radiation

Contrast Enhancement

</tbody>
</table>

Methods to Reduce the Risk of Contrast Induced Nephropathy

- Optimal: 0.9% NaCl at 1 ml/kg/hr for 12 hr pre-procedure and 12 hr post-contrast administration
- For same day procedure: 0.9% NaCl or NaHCO\(_3\) at 3 ml/kg/hr for 1-3 hr pre-procedure and for 6 hr post-contrast administration

Contraindications to IV Contrast

- MADD Failure
- Multiple myeloma
- Adverse reaction previously
- DM
- Dehydration
- Failure (renal, severe heart)
Chest X-Ray

Standard Views
- PA: anterior chest against film plate to minimize magnification of the heart size
- lateral: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
  - helps localize lesions when combined with PA view
- AP: for bedridden patients (generally a lower quality film than PA because of enlarged cardiac silhouette)
- lateral decubitus: to assess for pleural effusion and pneumothorax in bedridden patients; however, POCUS can also be utilized for both these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

Approach to CXR

Basics
- ID: patient name, MRN, sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)

Analysis
- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see Abdominal Imaging, MI10)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowels
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: lung parenchyma, pleura, diaphragm
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
Anatomy

Localizing Lesions for Parenchymal Lung Disease
- **silhouette sign**: loss of normal interfaces due to lung pathology (consolidation, atelectasis, mass), which can be used to localize disease in specific lung segments; note that pleural or mediastinal disease can also produce the silhouette sign
- **spine sign**: on lateral films, vertebral bodies should appear progressively radiolucent as one moves down the thoracic vertebral column; if they appear more radiopaque, it is an indication of pathology (e.g. consolidation in overlying left lower lobe)
- **air bronchogram**: branching pattern of air filled bronchi on a background of fluid filled airspaces

Figure 2. Location of fissures, mediastinal structures, and bony landmarks on CXR

Figure 3. Location of lobes of the lung
Computed Tomography Chest

Approach to CT Chest

- soft tissue window
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary
- bone window
  - vertebrae, sternum, manubrium, ribs: fractures, lytic lesions, sclerosis
- lung window
  - trachea: patency, secretions
  - bronchial trees: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma: fissures, nodules, fibrosis/interstitial changes
  - pleural space: effusions

Lung Abnormalities

Atelectasis

- pathogenesis: collapse of alveoli due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
    - post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
  - compressive
    - tumour, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
  - hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space
  - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax) to rule out a bronchogenic carcinoma

Consolidation

- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumour in alveoli
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign

DDx of Airspace Disease

- Pus (e.g. infections such as pneumonia, non-infectious inflammatory process)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchoalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)
• differential diagnosis
  - fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, BOOP, allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: bronchoalveolar carcinoma, lymphoma
• management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

Interstitial Disease
• pathogenesis: pathological process involving the interlobular connective tissue (i.e. “scaffolding of the lung”)
• findings
  - linear: fine lines caused by thickened connective tissue septae
    - Kerley A: long thin lines in upper lobes
    - Kerley B: short horizontal lines extending from lateral lung margin
    - Kerley C: diffuse linear pattern throughout lung
  - seen in pulmonary edema, lymphangitic carcinomatosis, and atypical interstitial pneumonias
  - nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
    - seen in malignancy, pneumoniais and granulomatous disease (e.g. sarcoidosis, miliary TB)
  - reticular (honeycomb): parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis
    - seen in IPF, asbestosis, and CVD
  - watch for pneumothorax as a complication
  - reticulonodular: combination of reticular and nodular patterns
    - may also see signs of airspace disease (atelectasis, consolidation)
• differential diagnosis
  - occupational/environmental exposure
    - inorganic: asbestosis, coal miner’s pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    - organic: hypersensitivity pneumonitis, bird fancier’s lung, farmer’s lung (moldy hay), and other organic dust
  - autoimmune: CVD (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IB, celiac disease, vasculitis
  - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), heroin, cocaine, methadone
  - infections: non-tuberculous mycobacteria, certain fungal infections
  - idiopathic: hypersensitivity pneumonitis, IPF, BOOP
• for Causes of Interstitial Lung Disease Classified by Distribution, see Respirology, R13
• management: high resolution CT thorax and biopsy

Pulmonary Nodule
• findings: round opacity ± silhouette sign
  - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
• differential diagnosis
  - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  - solitary nodule
    - tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
    - inflammation: histoplasmosis, tuberculosis, coccidioidomycosis
    - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
    - multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, GPA)
• management: clinical information and CT appearance determine level of suspicion of malignancy
  - if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/ transthoracic biopsy) is indicated
  - if low probability of malignancy, repeat CXR or CT in 1-3 mo and then every 6 mo for 2 yr; if no change, then >99% chance benign

Pulmonary Vascular Abnormalities

**Pulmonary Edema**
- pathogenesis: fluid accumulation in the airspaces of the lungs
- findings
  - vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
  - fluid initially collects in interstitium
    - loss of definition of pulmonary vasculature
    - peribronchial cuffing
    - Kerley B lines
    - reticulonodular pattern
    - thickening of interlobar fissures
  - as pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse air space disease often in a “bat wing” or “butterfly” pattern in perihilar regions with tendency to spare the outermost lung fields
- differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

**Pulmonary Embolism**
- pathogenesis: arterial blockage in the lungs due to emboli from pelvic or leg veins, rarely from PICC lines, ports, or air, fat, or amniotic fluid (difficult to diagnose on imaging except by combination of clinical history and CXR and CT findings of ARDS)
- findings
  - CXR: Westermark sign (localized pulmonary oligemia), Hampton’s hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
  - definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries (emboli can be seen up to 4th order arterial branching)
  - V/Q scan: not a diagnostic study

Pleural Abnormalities

**Pleural Effusion**

Table 6. Sensitivity of Plain Film Views for Pleural Effusion

<tr>
<td>PA</td>
<td>200 mL</td>
</tr>
<tr>
<td>Supine</td>
<td>Diffuse haziness</td>
</tr>
</tbody>
</table>

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis, and POCUS is now standard of care in acute situations
- fluid level >1 cm on lateral decubitus film is indication to perform thoracentesis

**Pneumothorax**
- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
• findings
  ▪ upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  ▪ more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiority)
  ▪ more difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, “double diaphragm” sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  ▪ mediastinal shift may occur if tension pneumothorax
  ▪ differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
  ▪ management: needle decompression or chest tube insertion, repeat CXR to ensure resolution

Asbestos
• asbestos exposure may cause various pleural abnormalities including benign plaques (most common) that may calcify, diffuse pleural fibrosis, effusion, and malignant mesothelioma

Mediastinal Abnormalities

Mediastinal Mass
• the mediastinum is divided into four compartments; this provides an approach to the differential diagnosis of a mediastinal mass
• anterior border formed by the sternum and posterior border by the heart and great vessels
  ▪ 4 Ts: see sidebar
  ▪ cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
• middle (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
  ▪ esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
• posterior (posterior to the middle line described above)
  ▪ neurogenic tumour (e.g. neurofibroma, schwannoma), multiple myeloma, pheochromocytoma, neurenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematomas
• superior boundaries (superiorly by thoracic inlet, inferiorly by plane of the sternal angle, anteriorly by manubrium, posteriorly by T1-T4, laterally by pleura)
• in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, and hematoma

Enlarged Cardiac Silhouette
• heart borders
  ▪ on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  ▪ on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
• cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
  ▪ using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
  ▪ differential of ratio >0.5
    ▪ cardiomegaly (myocardial dilatation or hypertrophy)
    ▪ pericardial effusion
    ▪ poor inspiratory effort/low lung volumes
    ▪ pectus excavatum
  ▪ ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
• pericardial effusion: globular heart with loss of indentations on left mediastinal border
• RA enlargement: increase in curvature of right heart border and enlargement of SVC
• LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and “double” heart border >7 cm, splayed carina (late sign)
• RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
• LV enlargement: displacement of cardiac apex inferiorly and posteriorly – “boot-shaped” heart
### Tubes, Lines, and Catheters

- Ensure appropriate placement and assess potential complications of lines and tubes
- Avoid mistaking a line/tube for pathology (e.g., oxygen rebreather mask for pneumothoraces)

#### Central Venous Catheter
- Used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- Tip must be located proximal to right atrium to prevent inducing arrhythmias or perforating wall of atrium
  - If monitoring CVP, catheter tip must be proximal to venous valves
- Tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- Course should parallel course of SVC – if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- Complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

#### Endotracheal Tube
- Frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- Progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- Tip should be located 4 cm above tracheal carina – avoids bronchus intubation and vocal cord irritation
- Maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture – ensure diameter of balloon is less than tracheal diameter above and below balloon
- Complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

#### Nasogastric Tube
- Tip and sideport should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- Radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- Complications: aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

#### Swan-Ganz Catheter
- To monitor pulmonary capillary wedge pressure and to measure cardiac output for suspected LV dysfunction
- Tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- If tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- Complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

#### Chest Tube
- In dorsal and caudal portion of pleural space to evacuate fluid
- In ventral and cephalad portions of pleural space to evacuate pneumothoraces
- Tube may lie in fissure as long as functioning
- Complications: lung perforation (mediastinal opacities)

### Abdominal Imaging

#### Abdominal X-Ray
- AXR 3 most common views: left lateral decubitus, supine, erect upright (see Figure 16)
- Indications
  - Acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
  - Chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
  - Not useful in: GI bleeds, chronic anemia, vague GI symptoms
Anatomy

- abdomen divided into 2 cavities
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

</tbody>
</table>

Approach to Abdominal X-Ray

- mnemonic: “Free ABDO”
- “Free”: free air and fluid
  - free fluid
    - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
    - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph and therefore cannot be differentiated
    - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon), penetrating trauma, or recent (<7 d) surgery
  - “A”: air in the bowel (can be normal, ileus, or obstruction)
    - volvulus – twisting of the bowel upon itself; from most to least common:
      - sigmoid: “coffee bean” sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal dilation
      - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
      - gastric: rare
      - transverse colon: rare (usually young individuals)
      - small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
    - toxic megacolon
      - manifestation of fulminant colitis
      - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps), loss of normal haustral pattern
  - “B”: bowel wall thickening
    - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall ("thumb-printing"), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
    - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
  - “D”: densities
    - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
    - abnormal calcifications: approach by location
      - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
      - RLQ: ureteral stone, appendicolith, gallstone ileus
      - LUQ: renal stone, adrenal calcification, tail of pancreas
      - LLQ: ureteral stone
      - central: aorta/aortic aneurysm, pancreas, lymph nodes
      - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
  - “O”: organs
    - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
    - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

</tbody>
</table>

Abdominal CT

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
  - portal venous phase: indicated for majority of cases
  - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
  - caution: contrast allergy (may premedicate with steroids and antihistamine)
  - contraindication: impaired renal function, based on eGFR
  - oral contrast: barium or water soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions

Biliary vs. Portal Venous Air

“Go with the flow”: air follows the flow of bile or portal venous blood
Biliary air is most prominent centrally over the liver
Portal venous air is most prominent peripherally

Figure 16. Normal AXRs: (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR
Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually, from top to bottom evaluating size and shape of each area of increased or decreased density
- evaluate the following
  - soft tissue window
  - liver, gallbladder, spleen, and pancreas
  - adrenals, kidneys, ureters, and bladder
  - stomach, duodenum, small bowel mesentery, and colon/appendix
  - retroperitoneum: aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels
  - peritoneal cavity for fluid or masses
  - abdominal wall and adjacent soft tissue
  - lung window
  - visible lung (bases)
  - bone window
  - vertebrae, spinal cord, and bony pelvis

CT and Bowel Obstruction

- cause of bowel obstruction rarely found on plain films – CT is best choice for imaging
- the “3,6,9” rule is a very useful guide to determining when the bowel is dilated; the maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel, and 9 cm for cecum; this can also be useful to distinguish small and large bowel, and to assess for ‘impending’ cecal perforation (e.g. post-untreated Ogilvie’s syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel segment obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

CT Colonography (virtual colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of obstructing colonic lesions

Contrast Studies

Table 10. Types of Contrast Studies

<table>
<thead>
<tr>
<th>Study</th>
<th>Organ</th>
<th>Procedure Description</th>
<th>Assessment</th>
<th>Findings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cine Esophagram</td>
<td>Cervical esophagus</td>
<td>Contrast agent swallowed recorded for later playback and analysis</td>
<td>Dysphagia, swallowing incoordination, recurrent aspiration, post-operative cleft palate repair</td>
<td>Aspiration, webs (partial occlusion), Zenker’s diverticulum, cricopharyngeal bar, laryngeal tumour</td>
</tr>
<tr>
<td>Barium Swallow</td>
<td>Thoracic esophagus</td>
<td>Contrast agent swallowed under fluoroscopy, selective images captured</td>
<td>Dysphagia, rule out GERD, post esophageal surgery</td>
<td>Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear</td>
</tr>
<tr>
<td>Upper GI Series</td>
<td>Thoracic esophagus, stomach, or duodenum</td>
<td>Double contrast study: 1. Barium to coat mucosa, then 2. Gas pills for distention Patient NPO after midnight</td>
<td>Dyspepsia, investigate possible upper GI bleed, weight loss/anemia, post gastric surgery</td>
<td>Ulcers, neoplasms, filling defects</td>
</tr>
<tr>
<td>Barium Enema</td>
<td>Large bowel Rectum may be obscured by tube – therefore must do sigmoidoscopy to exclude rectal lesions Colon filled retrograde with barium and air or CO₂ Bowel prep the night before procedure</td>
<td>Altered bowel habits, suspected lower GI bleed, weight loss/anemia, rule out large bowel obstruction, suspected perforation, check surgical anastomosis, history of polype</td>
<td>Diverticulosis, neoplasms, IBD, intussusception (can be reduced with barium or air enema), volvulus</td>
<td></td>
</tr>
<tr>
<td>Small Bowel Follow Through</td>
<td>Entire small bowel</td>
<td>Single contrast images following upper GI series</td>
<td>GI bleed with non-diagnostic upper GI series/barium enema, weight</td>
<td>Neoplasms, IBD, malabsorption, infection</td>
</tr>
<tr>
<td>Enteroclysis (MRI or CT)</td>
<td>Entire small bowel Enteroclysis: patient drinks 1-2 L of sorbitol, psyllium, or barium solution to distend small bowel Enteroclysis: NJ tube used to pump barium, psyllium, or sorbitol contrast media directly into small bowel</td>
<td>IBD, malabsorption, weight loss/anemia, Meckel’s diverticulum</td>
<td>Neoplasms, IBD, malabsorption, infection</td>
<td></td>

</tbody>
</table>
Specific Visceral Organ Imaging

Liver
- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumours, liver metastases, and other parenchymal conditions, and is particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- Elastography: measures shear wave velocity by U/S (Fibroscan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - portal HTN: increased portal vein diameter, collateral veins, splenomegaly (≥12 cm), portal vein thrombosis, recanalization of the umbilical vein
  - porto-systemic shunts: caput medusa, esophageal varices, spontaneous spleno-renal shunt
  - U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
  - CT: fatty infiltration appears hypodense
- in order to be visualized, some masses require contrast

</tbody>
</table>

Spleen
- U/S, CT: nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

Pancreas
- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
  - ductal dilation secondary to stone/tumour
  - MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
ERCP: endoscope to inject dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval); acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures.

**Biliary Tree**
- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. cholelithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

### “itis” Imaging

**Acute Cholecystitis**
- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or, in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see General Surgery, GS46)
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: thick wall, pericholecystic fluid, gallstones, dilated gallbladder, positive sonographic Murphy's sign
- management: cholecystectomy

**Acute Appendicitis**
- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see General Surgery, GS28)
- best imaging modality: U/S or CT
- findings
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: appendectomy

**Acute Diverticulitis**
- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see General Surgery, GS31)
- best imaging modality: CT is modality of choice, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel
- findings
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

**Acute Pancreatitis**
- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see Gastroenterology, G45); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings
  - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, stranding changes in surrounding fat with indistinct fat planes, mesenteric and Gerota’s fascia thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
  - CT-guided needle aspiration and/or drainage done for abscess when clinically indicated
  - pseudocyst may be followed by CT and drained if symptomatic
Chronic Pancreatitis
- pathogenesis: (see Gastroenterology, G45)
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland

Angiography of Gastrointestinal Tract
- anatomy of the GI tract arterial blood supply branches
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
    - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

Genitourinary System and Adrenal

Urological Imaging
KUB (Kidney, Ureter, and Bladder X-ray)
- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir), indwelling ureteric stents /catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

Abdominal CT
Renal Masses
- Bozniak classification for cystic renal masses
- class I-II: benign and can be disregarded
- class IIF: should be followed
- class III-IV: suspicious for malignancy, requiring additional workup

Table 13. Bozniak Classification for Cystic Renal Masses

<table>
<thead>
<tr>
<th>Classes</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple Renal Cysts</td>
<td></td>
</tr>
<tr>
<td>Class I</td>
<td>Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hair thin wall</td>
</tr>
<tr>
<td>Class II</td>
<td>Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (&lt;3 cm) that do not enhance with contrast</td>
</tr>
<tr>
<td>Complex Renal Cysts</td>
<td></td>
</tr>
<tr>
<td>Class III</td>
<td>Thick irregular walls ± calcifications ± septated, enhancing walls or septa with contrast</td>
</tr>
<tr>
<td>Renal Cell Carcinoma</td>
<td></td>
</tr>
<tr>
<td>Class IV</td>
<td>Same as class III + soft tissue enhancement with contrast (defined as &gt;10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis</td>
</tr>
</tbody>
</table>

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location), and hydropnephrosis prior to urological treatment
- CT urography indications: investigation of cause of microscopic/gross hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
- renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses, especially in differentiating renal cell carcinoma from more benign masses, and pre-operative staging
  - phases: unenhanced, arterial and venous (nephrographic), excretory

Figure 21. Triphasic CT of an angiomyolipoma: showing fat density with non-contrast scan, mildly enhancing with contrast

Angiography requires active blood loss 1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding

Imaging Modality Based on Presentation
- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloody urine = U/S, CT
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = HSG, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram
Ultrasound
- **indications**: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts); technique of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation to patient, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- **findings**: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

Retrograde Pyelography
- **indications**: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiograph or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
- **findings**: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

Voiding Cystourethrogram
- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time) to visualize bladder
- **indications**: children with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction or vesicoureteral reflux
- **findings**: contractility and evidence of vesicoureteric reflux

Retrograde Urethrogram
- a small Foley catheter placed into penile urethral opening
- **indications**: used mainly to study strictures or trauma to the male urethra; first-line study if trauma with blood present at urethral meatus

MRI
- **advantages**: high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
- **indications**: indicated over CT for depiction of renal masses in patients with previous nephron sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

Renal Nuclear Scan

<table>
<thead>
<tr>
<th>Type of Test</th>
<th>Uses</th>
<th>Radionuclide</th>
</tr>

</tr>
<tr>
<td>Morphological</td>
<td>Assess renal anatomy: investigation of pyelonephritis and cortical scars</td>
<td>(^{99m})Tc-DMSA, (^{99m})Tc-glucopentonate</td>
</tr>
</tbody>
</table>

Gynecological Imaging

Ultrasound
- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air containing loops of bowel
  - **indications**: good initial investigation for suspected pelvic pathology
- TVUS provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
  - **indication**: improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram
- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- **indications**: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

CT/MRI
- **indications**: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies and detecting recurrence

Figure 22. Triphasic CT of a renal cell carcinoma: showing arterial enhancing right renal lesion with venous washout (shunting)

Figure 23. Retrograde urethrogram: demonstrating stricture in the membranous urethra

Figure 24. Transabdominal U/S: pregnancy, 18 wk fetus

Figure 25. Hysterosalpingogram: left hydrosalpinx

Pregnancy should always be ruled out by \(\beta\)-hCG before CT of a female pelvis (or any organ system) is performed
Sonohysterogram
- saline infusion sonohysterogram involves instilling fluid into the uterine cavity transcervically to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

Table 15. Typical and Atypical Findings on a Sonohysterogram

<table>
<thead>
<tr>
<th>Finding</th>
<th>Typical</th>
<th>Atypical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polyps</td>
<td>A well-defined, homogeneous, polypoid lesion isoechoic to the endometrium with preservation of the endometrium-myometrial interface</td>
<td>Atypical features include cystic components, multiple polyps, broad base, hypeoecogenicity or heterogeneity</td>
</tr>
<tr>
<td>Leiomyoma</td>
<td>Well-defined, broad-based, hypeoecogenic, solid masses with shadowing. Overlying layer of endometrium is echogenic and distorts the endometrium-myometrial interface</td>
<td>Pedunculation or multilobulated surface</td>
</tr>
<tr>
<td>Hyperplasia</td>
<td>Diffuse echogenic endometrial thickening without focal abnormality, although focal lesions can occur. Endometrial cancer is typically a diffuse process, but early cases can be focal and appear as a polypoid mass</td>
<td></td>
</tr>
<tr>
<td>Cancer</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Adhesions</td>
<td>Mobile, thin, echogenic bands that cut across the endometrial cavity</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Thick, broad-based bands that can completely obliterate the endometrial cavity, as in Asherman’s syndrome</td>
<td></td>
</tr>
</tbody>
</table>

Adrenal Mass
- imaging modality: most often identified on CT scan as ‘incidentaloma,’ can also use CT/MRI to distinguish benign from malignant masses

Table 16. Adrenal Mass Findings on CT and MRI

Neuroradiology

Modalities
- CT is the modality of choice for most neuropathology; even under circumstances when MRI is preferred, CT is frequently the initial study performed because of its speed, availability, and lower cost
  - acute head trauma: CT is best for visualizing “bone and blood”; MRI is used only when CT fails to detect an abnormality despite strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - suspected subarachnoid or intracranial hemorrhage
  - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
  - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumours, respectively

Figure 26. Epidural hematoma
**Skull Films**
- rarely performed, generally not indicated for non-penetrating head trauma
- **indications**: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys

**CT**
- **indications**: excellent study for evaluation of bony and intracranial abnormalities
- often done first without and then with IV contrast to show vascular structures or anomalies
- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
  - when in doubt, look for circle of Willis or confluence of sinuses to determine presence of contrast enhancement
- posterior fossa can be obscured by extensive bony-related streak artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with newer generation of multidetector CT scanners

**Myelography**
- introduction of water-soluble, low-osmotic contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
- **indications**: excellent study for disc herniations, traumatic nerve root avulsions, patients with contraindication to MRI

**MRI**
- **indications**: shows brain and spinal soft tissue anatomy in fine detail, clearly distinguishes white from grey matter (especially T1-weighted series), multiplanar reconstruction helpful in pre-operative assessment

**Cerebral Angiography/CT Angiography/MR Angiography**
- **indications**: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
- conventional DSA remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without actual risk to intracranial or neck vessels
- MRA and CTA are often used first as ‘screening tests’ for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

**Nuclear Medicine**
- SPECT using $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within neurons proportional to cerebral blood flow
- $^{18}$FDG PET imaging assesses cerebral metabolic activity
- **indications**: differentiation of residual tumour vs. radiation necrosis; localizing of epileptic seizure foci; evaluation of atypical dementia
Approach to CT Head

- think anatomically, work from superficial to deep
- scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
- skin/soft tissue: examine the soft tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid, muscles of mastication (masseter, temporalis, pterygoids), visualized pharynx
- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture; status of the orbital floor in cases of facial trauma (coronal series best)
- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between grey and white matter suggests possible infarction, tumour, edema, infection, or contusion; hyperdensity in the parenchyma suggests enhancing lesions, intracerebral hemorrhage, or calcification; central grey matter nuclei (e.g. globus pallidus, putamen, internal capsule) should be visible, otherwise, suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour

Selected Pathology

- see Neurosurgery, NS4 for intracranial mass lesions
- see Neurosurgery, NS29 and Plastic Surgery, PL28 for head trauma
- see Emergency Medicine, ER9 for vertebral trauma
- see Neurosurgery, NS27 and Orthopedics, OR23 for degenerative spinal abnormalities

Cerebrovascular Disease (see Neurology, N46 and Neurosurgery, NS17)

- pathogenesis of stroke: see Neurology, N46
- best imaging modality: infarcts best detected by MRI > CT
- findings of infarction
  - early changes
    - CT
      - usually normal within 6 h of infarction
      - edema (loss of grey-white matter differentiation – “insular ribbon” sign, effacement of sulci, mass effect)
      - within 24 h, development of low-density, wedge-shaped area of infarction extending to periphery (correlating to vascular territory distal to affected artery)
      - in case of ischemic stroke, may see hyperattenuating (bright) artery (hyperdense MCA sign) representing intravascular thrombus or embolus
      - in case of hemorrhagic stroke or transformation (common in basal ganglia and cortex), may see bright acute blood surrounded by edema
    - MRI
      - edema with high signal on T2-weighted images and FLAIR image (loss of grey-white matter differentiation, effacement of sulci, mass effect)
      - DWI shows acute high signal changes demonstrating restricted movement of water indicative of cytotoxic edema; usually indicates stroke damage before CT
      - apparent diffusion coefficient image shows low signal intensity in acute ischemia (nadir 3-5 d, returns to baseline 1-4 wk)
  - subacute changes on CT and MRI
    - edema and mass effect more prominent
  - gyral enhancement with contrast indicative of blood-brain barrier breakdown
  - chronic changes on CT and MRI
    - encephalomalacia (parenchymal volume loss) with dilatation of adjacent ventricles
  - carotid artery disease
    - best imaging modality: Duplex Doppler U/S
    - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)
Multiple Sclerosis (refer to Neurology, N51)
- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
  - characteristic lesion on MRI is cerebral or spinal plaque
  - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum), centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  - “Dawson’s fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be of use
  - perivascular and interstitial edema may be prominent
  - spinal cord lesions typical of MS
    - little or no cord swelling
    - unequivocal hyperintensity on T2-weighted sequences
    - size at least 3 mm but less than 2 vertebral segments in length
    - occupy only part of the cord in cross-section
    - focal (i.e. clearly delineated and circumscribed on T2-weighted sequences)

CNS Infections
- leptomenigitis
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: S. pneumoniae, H. influenzae, N. meningitidis, L. monocytogenes
  - best imaging modality: MRI (T2-weighted/FLAIR) superior to CT
  - findings
    - meningeal enhancement (following the gyri/sulci, and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
    - a normal MRI does not rule out leptomeningitis
- herpes simplex encephalitis (see Infectious Diseases, ID18)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2-weighted)
  - findings
    - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
    - DDx: infarct, tumour, status epilepticus, limbic encephalitis
    - CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
    - long-term may show parenchymal loss to affected areas
- cerebritis/cerebral abscess
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: S. aureus (often in IV drug users, nosocomial), Streptococcus, Gram negative bacteria, Bacteroides
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2
Musculoskeletal System

Modalities

- refer to MI2 for advantages and disadvantages of the following imaging modalities

Plain Film/X-Ray
- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malalignment, orthopedic hardware, and bone tumours (initial)
- minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- image proximal and distal joints (particularly important with paired bones (e.g. radius/ulna)
- minimally effective in evaluating soft tissue injury

CT
- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification

MRI
- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses

Ultrasound
- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, U/S guided biopsy and injections
- Doppler determines vascularity of structures

Nuclear Medicine (Bone Scintigraphy)
- determine the location and extent of bony lesions
- $^{99m}$Tc-methylene diphosphonate localizes to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget's), sites of reactive bone formation, and periostitis
- advantages: very sensitive, capable of imaging entire body with relatively low dose radiation
- disadvantages: low specificity, not widely available due to special requirements (e.g. gamma camera, radiopharmaceuticals)

Approach to Bone X-Rays

- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

Trauma

Fracture/Dislocation
- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR5
Arthritis

Radiographic Hallmarks of Osteoarthritis
- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of Rheumatoid Arthritis
- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

Bone Tumour

Approach
- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 yr
  - diagnosis usually requires a biopsy if primary not located
  - few benign tumours/lesions have potential for malignant transformation
  - MRI is good for tissue delineation and pre-operative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
  - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

Considerations and Tumour Characteristics
- for specific bone tumours, see Orthopedics, OR46
- age – most common tumours by age group
  - <1 yr of age: metastatic neuroblastoma
  - 1-20 yr of age: Ewing’s sarcoma in tubular bones
  - 10-30 yr of age: osteosarcoma and Ewing’s tumour in flat bones
  - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
  - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
  - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
  - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumours, eosinophilic granuloma, Ewing’s sarcoma
- expansile
  - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
- matrix mineralization
  - chondroid (popcorn calcification) or osseous
- margin/zone of transition: area between lesion and normal bone
  - cortex: intact, disturbed
  - periosteal reaction
  - soft tissue mass

Figure 38. Rheumatoid arthritis (A) compared with osteoarthritis (B) changes on X-ray

Benign Lesions which may have Aggressive Features
- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

Periosteal Reaction
- “Onion skinning” = Ewing’s sarcoma
- “Sunburst”, “hair on end” = osteosarcoma
- “Codman’s triangle” = osteosarcoma, Ewing’s sarcoma, subperiosteal abscess

</tbody>
</table>
Metastatic Bone Tumours
- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumours
- metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial workup
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- most common metastatic bone tumours: breast, prostate, lung, see Orthopedics, OR46

Infection

Osteomyelitis
- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- ⁹⁹ᵐTc, followed by ¹¹¹In labeled white cell scan or gallium radioisotope scan
- plain film changes visible 8-10 d after process has begun
  - soft tissue swelling
  - local periosteal reaction
  - pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fasciitis
  - mottled and nonhomogeneous with a classic “moth-eaten” appearance
  - cortical destruction

Bone Abscess
- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie's abscess
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone
- best modality: MRI for bone, bone marrow, and soft tissue abnormalities; CT for sequestra and cortical erosions

Metabolic Bone Disease

Osteoporosis
- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- DEXA: gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: $-2.5 < T\text{-score} < -1$
    - osteoporosis: $T\text{-score} \leq -2.5$
  - Z-score: the number of standard deviations from the age-matched mean
  - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
  - diagnostic sensitivity of DEXA highest when bone mineral density measured at lumbar spine and proximal femur
- appearance on plain film
  - osteopenia: reduced bone density on plain films
  - may also be seen with osteomalacia, hyperparathyroidism, and disuse
  - compression of vertebral bodies
  - biconcave vertebral bodies (“codfish” vertebrae)
  - long bones have appearance of thinned cortex and increased medullary cavity
  - look for complications of osteoporosis (e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami)
- see Endocrinology, E38
Osteomalacia/Rickets
- reduction in bone mineral density; normal amount of bone, but reduced mineralization of normal osteoid
- usually due to vitamin D deficiency, resulting in softening and bowing of long bones
- similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
- “fuzzy”, ill-defined trabeculae
- Looser’s zones (pseudofracture)
  - characteristic radiologic feature
  - fissures or clefs at right angles to long bones and extending through cortex
  - DDx: chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget's, osteodystrophy, X-linked hypophosphataemia

Hyperparathyroidism
- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis
  - calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and periarticular soft tissue)
  - resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumours)
  - “rugger jersey spine”: band-like osteosclerosis at superior/inferior margins of vertebral bodies
- see Endocrinology, E38

Paget’s Disease
- abnormal remodeling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- features
  - coarsening of the trabeculae with bone expansion
  - bone softening/bowing
  - bone scan will reveal high activity, especially at bone ends
  - thickened cortex
- see Endocrinology, E42
Brain

- $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism, taken up predominantly in grey matter; used for dementia, traumatic brain injury and to a lesser extent vasculitis, neuropsychiatric disorders and occasionally stroke; also the most commonly used tracers to confirm brain death (i.e. absent blood flow to the brain and absent uptake on delayed planar and SPECT images in brain and brainstem, assuming study is technically adequate); either tracer can be used for seizure imaging to assess for the most likely location of epileptogenic focus but usually must be made available for 24 hr and the patient followed by a nurse who is competent to administer the activity at the time of seizure.

- PET imaging assesses metabolic activity most commonly with $^{18}$FDG; used for dementia imaging, grade and stage of brain tumours, occasionally for seizure disorder imaging, and vasculitis; PET imaging with amyloid tracers for diagnosis of Alzheimer’s disease is becoming more common.

- CSF imaging, intrathecal administration of $^{111}$In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy.

- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free $^{99m}$Tc (usually) or $^{111}$In-DTPA; small quantity of activity is injected into the reservoir under sterile conditions and should flow freely into the peritoneal cavity by 45 min; maneuvers such as pumping the shunt, sitting the patient upright or ambulating are acceptable to encourage flow during this time.

- Adrenergic imaging of the heart with MIBG has been used to differentiate dementias with autonomic dysfunction (i.e. Lewy Body and Parkinson’s disease) from other forms of dementia (i.e. autonomic impairment associated with decreased MIBG activity in the heart).

Thyroid

Radioactive Iodine Uptake (see Endocrinology, E20)

- index of thyroid function (trapping and organification of iodine)
- radioactive $^{131}$I given PO to fasting patient (small quantity)
- measure percentage of administered iodine taken up by thyroid
- increased RAU: toxic multinodular goitre, toxic adenoma, Graves’ disease
- decreased RAU: subacute thyroiditis, late Hashimoto’s disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking a “thyroid vitamin”)
- Important – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism (exception is pediatrics)

Thyroid Imaging (Scintiscan)

- $^{99m}$Tc-pertechnetate IV or radioactive iodine ($^{123}$I); most Canadian sites use pertechnetate to reduce cost
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer very unlikely (less than 1%)
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous; decision to biopsy should be based on clinical and sonographic features
- isointense i.e. “warm” lesions: cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

Radioiodine Ablation

- $^{131}$I for Graves’ disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient that has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

Pediatric Hypothyroidism

- Pertechnetate thyroid scan can differentiate thyroid agenesis, hemiagenesis, lingular thyroid, organification defect, however should not wait for a diagnosis to start thyroid hormone replacement in a neonate; start immediately.
Respiratory

V/Q Scan
examine areas of lung in which ventilation and perfusion do not match

- ventilation scan
  - patient breathes radioactive gas (nebulized 99mTc-DTPA, 133Xe, or most commonly Technegas) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction

- perfusion scan
  - radiotracer injected IV (99mTc-MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
  - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, small child. In these cases fewer particles are usually given
  - to rule out PE
    - indications: some institutions favour in pregnancy (lower radiation dose to breast than CT), or where CT contrast contraindicated (e.g. contrast allergy, renal failure)
    - areas of lung are well ventilated but not perfused (unmatched defect) are suspicious for acute infarction
    - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
    - often reported as high probability (>2 large i.e. segmental mismatched perfusion defects), intermediate, low, very low, or normal according to modified PIOPED II criteria although now are increasingly reported as PE present, indeterminate or normal
    - useful in finding clinically important emboli
    - decreased detection of incidentalalomas commonly found on CT
  - not valid for assessment of PE when patients have consolidation and the test can be limited by ventilatory problems (e.g. COPD), much like CT
  - modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

Cardiac

Myocardial Perfusion Scanning
- to investigate coronary artery disease (CAD), assess treatment of CAD, pre op risk stratification, viability testing
- 99mTc-sestamibi, or 99mTc-tetrofosmin are used most commonly, thallium 201 was used previously but largely discontinued due to high radiation doses to patients and unfavourable imaging characteristics; today thallium still used for viability studies
- injected at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes) or after persantine challenge (vasodilator), or dobutamine infusion (chronotropic, again to 85% predicted heart rate); can be done as stress only protocol with optional rest or as stress and rest combined protocol (i.e. as 1 day or 2 day protocol).
- patients with left bundle usually given pharmacologic stress because EKG is difficult to interpret for ST changes and avoids a characteristic artifact
- pharmacologic stress contraindicated if BP is < 90 systolic; persantine exacerbates asthma, so patients with asthma and wheeze who cannot exercise usually get dobutamine infusion; reverse persantine with aminophylline or caffeine
- persistent defect (at rest and stress) suggests infarction or myocardial scar; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- Courage trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see Cardiology and Cardiac Surgery, C13

Radionuclide Ventriculography
- 99mTc tagged to red blood cells, tagged albumin is also acceptable
- first pass through RV → pulmonary circulation → LV; provides information about RV function, presence of shunts
- cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
- evaluation of LV function and regional wall motion, ejection fraction
- images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
- can assess diastolic dysfunction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion
- indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator work up
HIDA Scan (Cholescintigraphy)
- IV injection of $^{99m}$Tc-disofenin (DISIDA) or $^{99m}$Tc-mebrofenin which is bound to protein, taken up, and excreted by hepatocytes into biliary system.
- can be performed in non-fasting state but prefer NPO after midnight
- indicated in workup of cholecystitis when abdominal ultrasound result is equivocal:
  - acute cholecystitis: no visualization of gallbladder at 4 h or 1 hour after administration of morphine
  - chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- gallbladder visualized when cystic duct is patent (rules out acute cholecystitis with >99% certainty), usually seen by 30 min to 1 h
- differential diagnosis of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
- also used to assess bile leaks post-operatively or in trauma
- gallbladder ejection fraction (>38% is normal) can be measured after a fatty meal or CCK to assess for biliary dyskinesia

RBC Scan
- IV injection of radiotracer with sequential images of the abdomen ($^{99m}$Tc RBCs)
- GI bleed
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image, requires active bleeding to localize
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific)
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills in later (accumulation of tagged cells greater than surrounding liver parenchyma)

Other Important Nuclear Medicine Abdominal Tests
- Meckel's Scan: uses Tc 99m pertechnetate; give patient ranitidine premedication; Meckel's diverticulum contains gastric mucosa which will light up at the same time as the stomach and get brighter with time like stomach
- Indium 111 octreoscan: a somatostatin analog used for evaluation and staging of neuroendocrine tumours including carcinoid; gastrinoma and carcinoid tend to be more octreotide avid than insulinoma.
- Iodinated MIBG: a norepinephrine analog, used for pheochromocytoma, neuroblastoma and medullary thyroid cancer most commonly; limited cardiac applications as above
- solid and liquid gastric emptying: a standardized solid or liquid meal is labelled, usually with Tc 99m sulfur colloid and gastric emptying studied over time. There are normal ranges for solids and liquids

Urea Breath Test
- indication: diagnosis of gastric Helicobacter pylori infection
- patient administered $^{14}$C-labelled urea orally, urea metabolized by H. pylori to ammonia and $^{14}$CO$_2$. $^{14}$C-labeled CO$_2$ is measured via plastic filament detectors or liquid scintillation

Functional Renal Imaging
- evaluation of renal function and anatomy using $^{99m}$Tc DTPA or Tc 99m MAG3
- frequently used to provide index of relative function between two kidneys
- frequently used in adults to assess for UPJ obstruction (by assessing the clearance half time with lasix), and assess renal transplants or as a nuclear GFR study in patients wanting to donate kidneys
- in children, imaging with Tc 99m DMSA is used to assess for pyelonephritis
- in children, the injection of tracer into the bladder via foley catheter is often used to assess for reflux

Bone Scan
- isotopes, usually $^{99m}$Tc-diphosphonate
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone pain of unknown origin, staging or restaging of cancer with boney mets (or primary bone cancer), imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- differential diagnosis of positive bone scan: bone metastases (breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget’s disease
- lytic lesions like multiple myeloma, renal cell cancer, eosinophilic granuloma: typically normal or cold (false negative); need a skeletal survey
- “superscan”: increased bone uptake and poor renal uptake due to diffusion
- infiltration of prostate or metabolic causes (i.e. renal osteodystrophy)

**Interventional Radiology**

**Vascular Procedures**

**Angiography**
- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a “fluor” or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see Neuroradiology, MI18

**Percutaneous Transluminal Angioplasty and Stents**
- introduction and injection of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5-yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty
- stents are also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
- complications: similar to angiography, but also includes vessel rupture

**Thrombolytic Therapy**
- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
- complications: bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

**Embolization**
- injection of occluding material into vessels
- permanent agents: amplatzers plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

**Inferior Vena Cava Filtre**
- insertion of metallic “umbrellas” to mechanically trap emboli and prevent PE
- may be temporary (retrievable) or permanent
- inserted via femoral vein, jugular vein, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation
Central Venous Access
- variety of devices available
  - PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®)
  - indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
  - complications: venous thrombosis and central venous stenosis, infection including sepsis, pneumothorax

Nonvascular Interventions

Percutaneous Biopsy
- replaces open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy, CT or MR guidance
- complications: false negative (sampling error or tissue necrosis), pneumothorax in 30% of lung biopsies (chest tube required in ~5%), acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

Abscess Drainage
- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening structures (e.g. bowel), bacteremia, sepsis

Percutaneous Biliary Drainage/Cholecystostomy
- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
  - cholecystostomy: acute cholecystitis
  - PBD: biliary obstruction secondary to stone or tumour, cholangitis
- complications
  - acute: sepsis, hemorrhage
  - long-term: tumour ingrowth and stent occlusion

Percutaneous Nephrostomy
- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy
- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: inability to eat (most commonly CNS lesion e.g. stroke) or esophageal obstruction, decompression in gastric outlet obstruction
- complications: gastrosophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency Ablation
- U/S or CT guided probe is inserted into tumour, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours
- complications: destruction of neighbouring tissues and structures, bleeding
Breast Imaging

Modalities

Mammography

Description
• x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General Surgery, GS54)
• routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

Indications
• screening
  ▪ begin screening from age 50 q2 yr
  ▪ no strong data to support screening >70 yr, but may continue screening if in good general health
  ▪ if <50, screening is only recommended for those with high risk of breast cancer
  ▪ screening detects 2-8 cancers/1,000 women screened
• surveillance
  ▪ follow-up of women with previous breast cancer
• diagnostic: includes mammography with special views and/or ultrasound
  ▪ work-up of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
  ▪ women with abnormal screening mammograms
  ▪ suspected complications of breast implants

Breast Ultrasound

Indications
• characterization of palpable abnormalities (ultrasound 1st line <30 yr and in lactating and pregnant women, >30 yr need mammogram 1st)
• further characterization of mammographic findings
• guidance for interventional procedures

Breast MRI

Description
• contrast enhanced MRI of the breasts
• sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
• for diagnosis, used only after mammography and U/S investigation
• use as a screening modality is limited to high risk patients, in conjunction with mammography

Indications
• “problem solving” of indeterminate findings following complete mammographic and ultrasound work up
• evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
• evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
• High Risk Screening
  ▪ known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer or untested first-degree relative of a carrier of such a gene mutation
  ▪ family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
  ▪ high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
  ▪ radiation therapy to chest (before age 30)
**Breast Interventional Procedures**

**Description**
- Includes fine needle aspirate biopsy, core needle biopsy, stereotactic biopsy, MRI guided biopsy, abscess drainage, and cyst aspiration (see General Surgery, GS54)

**Indications**
- Cystic mass: complex cyst, symptomatic, suspected abscess
- Solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5)
- Suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) – stereotactic biopsy
- Initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- Percutaneous wire localization of a lesion generally recommended

**Breast MASSES**
- Definition: a space occupying lesion seen in two different projections; if seen in only a single projection it should be called an “asymmetry” until its three-dimensionality is confirmed

**Table 21. Mammographic Features of Benign and Malignant Breast Masses**

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>Radiolucent (oil cyst, lipoma, fibrolipoma, galactoceles, hamartoma)</td>
<td>Radiodense</td>
<td></td>
</tr>
</tbody>
</table>

**Calcifications (± mass)**
- Popcorn (fibrinoid adenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered
- Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogeneous, regional, segmental, clustered

**Other Findings**
- Tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- Intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- Focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
  - If focal compression shows mass-like character, or if the area can be palpated, biopsy generally recommended

Anatomy of the Kidney

- see Urology, U2

Renal Structure and Function

The Nephron
- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

The Glomerulus
- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman’s space
- particles are selectively filtered by size (<60 kDa) and charge (negative charge repelled)
- consists of following cell types
  1. Mesangial cells
     - structural cells that support the vascular tree; they are also contractile and produce vasoactive substances to help control blood flow
  2. Capillary endothelial cells
     - one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their sinusoidal nature and glycocalyx; contribute to the production of the GBM
  3. Visceral epithelium (podocytes)
     - one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their interdigitated foot process that form slit diaphragms; contribute to the production of the GBM
  4. Parietal epithelium
     - lines the interior of Bowman’s capsule and contains a podocyte progenitor population
  5. Juxtaglomerular cells
     - smooth muscle cells in lining of afferent arteriole; produce, store and secrete renin
The Renal Tubules

- Reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion.
- Each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics.

**Figure 1. The glomerulus**

**Renal Hemodynamic Parameters**

- RBF = 20% of CO, ~1 L/min
- RPF = RBF*(1-Hct)
- GFR = ~120 mL/min in healthy adult
  (99% of this volume is reabsorbed)
- FF = GFR/RPF (normally 20%)

**Figure 2. Tubular segments of the nephron**

- Avoid NSAIDs in patients with diarrhea, heart failure, or renal failure.
Renal Hemodynamics

- **GFR**
  - the rate of fluid transfer between glomerular capillaries and Bowman’s space
  - 180 L/d, of which 99% is reabsorbed, giving a daily urine output of 1.0-1.5 L
  - normal urine output is 0.5-2.0 ml/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter

- **renal autoregulation** maintains constant GFR over mean arterial pressures of 70-180 mmHg

- 2 mechanisms of autoregulation
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. ↑ perfusion pressure → afferent arteriolar constriction → ↓ GFR)
  - tubuloglomerular feedback: changes in Na+ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. increased delivery causes afferent constriction)

- **FF**
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%

- angiotensin II constricts renal efferent arterioles which increases FF, thereby maintaining GFR

- renin is released from juxtaglomerular apparatus in response to decreased RPF

---

**Figure 3. Renin-angiotensin-aldosterone system**

**Assessment of Renal Function**

**Measurement of Renal Function**

- **GFR** = rate of filtration of plasma by the glomeruli
- most renal functions decline in parallel with a decrease in GFR
- inulin clearance is the gold standard for measuring GFR, but very rarely used clinically
- clinically, GFR is estimated using serum creatinine concentration, [Cr]
- Cr is a metabolite of creatine (intermediate in muscle energy metabolism)
- Cr is freely filtered at the glomerulus with no tubular reabsorption
- tubular secretion varies based on level of renal function (10% to >50%)
- increased muscle mass increases rate of production of Cr
- Cr filtered = Cr excreted (at steady state)

**Ways to Estimate GFR Using Serum Creatinine Concentration**

1. **Measure CrCl**
   - calculation provides reasonable estimate of GFR
   - measure plasma [Cr], 24 h urine volume, and urine [Cr]
   - GFR/d = ([urine [Cr] x urine volume]/d)/(plasma [Cr])
   - must use same units for urine [Cr] and plasma [Cr]

2. **Estimate CrCl using Cockcroft-Gault formula**
   - serum Cr used along with age, gender, and weight (kg) to estimate GFR
   - normal range is >90 mL/min (>1.5 mL/s)

**Cockcroft-Gault Formula**

\[
\text{CrCl (mL/min)} = \frac{(weight \text{ in kg} \times 1.23 \times [Cr]_{\text{plasma}})}{(140 \text{ age} - weight \text{ in kg})} \times 0.85 \text{ for females}
\]
3. Estimate GFR using MDRD formula
   - most common way in which GFR is estimated (MDRD 7 equation)
     - complex formula incorporating age, gender, serum Cr, and African descent, but does not
       include weight
     - GFR is reported as mL/min/1.73 m² body surface area

4. Estimate GFR using CKD-EPI equation
   - the best current equation
     - calculated using serum Cr, age, sex, and race

Limitations of Using Serum Cr Measurements
1. must be in steady state
   - constant GFR and rate of production of Cr from muscles
   - sudden injury may reduce GFR substantially, but it takes time for Cr to accumulate and then
     re-establish steady state
   - clinical correlation: in AKI, the rise in Cr is often delayed
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
   - with progressive renal failure, remaining nephrons compensate with hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
   - lower production with smaller muscle mass (e.g. female, elderly, low weight)
     - for example, consider plasma [Cr] of 100 µmol/L in both of these patients
       - 20 yr old man who weighs 100 kg, GFR = 144 mL/min
       - 80 yr old woman who weighs 50 kg, GFR = 30.6 mL/min
     - clinical correlation: GFR decreases with age and would not be reflected as a rise in serum Cr
       due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
   - serum Cr and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement
   - very high bilirubin level causes [Cr] to be falsely low
   - acetocetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

Measurement of Urea Concentration
- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified
  by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or
  catabolism (sepsis, trauma, GI bleed) causes urea level to rise
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states such as ECF volume depletion
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and µmol/L for Cr)

Urinalysis
- use dipstick in freshly voided urine specimen to assess the following:

1. Specific Gravity
   - ratio of the mass of equal volumes of urine/H₂O
   - range is 1.001 to 1.030
   - values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
   - value usually 1.010 in ESRD (isosthenuria: same specific gravity as plasma)

2. pH
   - urine pH is normally between 4.5-7.0; if persistently alkaline, consider
     - RA
     - UTI with urease-producing bacteria (e.g. Proteus)

3. Glucose
   - freely filtered at glomerulus and reabsorbed in proximal tubule
   - causes of glucosuria include
     1. hyperglycemia >9.11 mmol/L leads to filtration that exceeds tubular resorption capacity
     2. increased GFR (e.g. pregnancy)
     3. proximal tubule dysfunction (e.g. Fanconi’s syndrome)

4. Protein
   - dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
   - microalbuminuria (defined as ≥2.0 mg/mmol Cr in males and ≥2.8 mg/mmol Cr in females) is
     not detected by standard dipstick (see Diabetes, NP28)
   - sulfosalicylic acid detects all protein in urine by precipitation
   - gold standard: 24 h timed urine collection for total protein
5. Leukocyte Esterase
- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation (e.g. AIN)

6. Nitrites
- nitrates in urine are converted by some bacteria to nitrites
- high specificity, low sensitivity for UTI

7. Ketones
- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. Hemoglobin
- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

### Urine Microscopy
- centrifuge urine specimen for 3-5 min, discard supernatant, resuspend sediment and plate on slide
- shaking tube vigorously may disrupt casts

<table>

</tbody>
</table>

1. CELLS

**Erythrocytes**
- normal range = up to 2-3 RBCs per HPF
- hematuria = greater than 2-3 RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
- isomorphic RBCs, no casts suggest extraglomerular bleeding (e.g. bladder Ca)

**Leukocytes**
- normal range = up to 3 WBCs per HPF
- pyuria = greater than 3 WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, papillary necrosis, renal TB, viral infections

**Eosinophils**
- detected using Wright’s or Hansel’s stain (not affected by urine pH)
- consider AIN, atheroembolic disease

**Oval Fat Bodies**
- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

2. CASTS
- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

<table>
<thead>

</tbody>
</table>
3. CRYSTALS
- uric acid: consider acid urine, hyperuricosuria
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning
- sulfur: sulfa-containing antibiotics

**Urine Biochemistry**
- commonly measure: Na⁺, K⁺, Cl⁻, osmolality, and pH
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:
  1. ECF volume depletion: expect low urine [Na⁺] (kidneys should be retaining Na⁺)
     - i.e. high urine [Na⁺] (>40 mmol/L) in the setting of AKI: suggests renal disease
     - i.e. high urine [Na⁺] (>40 mmol/L) in the setting of hyponatremia: generally from causes such as diuretics, tubular disease (e.g. Bartter's syndrome), SIADH
  - urine [Na⁺] <20 mmol/L suggests a prerenal problem
  - i.e. high urine [Na⁺] (>40 mmol/L) in the setting of AKI: suggests renal disease
  - i.e. high urine [Na⁺] (>40 mmol/L) in the setting of hyponatremia: generally from causes such as diuretics, tubular disease (e.g. Bartter's syndrome), SIADH
  2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
     - if higher than 20 mmol/d, suggests renal contribution to hypokalemia
  - osmolality is useful to estimate the kidney's concentrating ability
  - FENa refers to the fractional excretion of Na⁺
  - FEₙa = urine [Na⁺] x plasma [Cr] / (plasma [Na⁺] x urine [Cr])
  - FEₙa <1% suggests the pathology is prerenal
  - urine pH is useful to grossly assess renal acidification
  - a low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA)

**Electrolyte Disorders**

### Sodium Homeostasis
- hyponatremia and hypernatremia are disorders of water balance
- hyponatremia usually suggests too much water in the ECF relative to Na⁺ content
- hypernatremia usually suggests too little water in the ECF relative to Na⁺ content
- solutes (such as Na⁺, K⁺, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
- water moves out of cells in response to increased ECF osmolality
- water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na⁺ content rather than concentration
- Na⁺ deficiency leads to ECF volume contraction
- Na⁺ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially in the brain) shrinking (hyponatremia) or swelling (hyponatremia)

<table>

*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia
Hyponatremia

Hyponatremia: serum [Na⁺] < 135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is “appropriate” vs. “inappropriate” ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

Signs and Symptoms
- depend on degree of hyponatremia and more importantly, velocity of progression from onset
- hyponatremia = swollen cells
- acute hyponatremia (<24-48 h) more likely to be symptomatic
- chronic hyponatremia (>24-48 h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
  - adaptation is responsible for the risks associated with overly rapid correction
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

Complications
- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)

Risk Factors for Osmotic Demyelination
- rise in serum [Na⁺] with correction > 8 mmol/L/d if chronic hyponatremia
- associated hypokalemia and/or malnutrition (e.g. low muscle mass)
- if patient with hyponatremia and hypovolemia is given large volume of isotonic fluid (ADH is stimulated by hypovolemia); when hypovolemia is corrected, the ADH level falls suddenly causing sudden brisk water diuresis, and therefore rapid rise in serum Na⁺ level
- patient with psychogenic polydipsia, deprived of water

Investigations
- ECF volume status assessment (see Table 4)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine Na⁺ (urine Na⁺ < 10-20 mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 5)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH
Treatment of Hyponatremia
- general measures for all patients
  1) treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
  2) restrict free water intake
  3) promote free water loss
  4) carefully monitor serum Na⁺, urine volume, and urine tonicity
  5) ensure frequently that correction is not occurring too rapidly
    - monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia

A. Known Acute (known to have developed over <24-48 h)
- commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum [Na⁺] = 125-130 mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on severity
  - if marked fall in plasma [Na⁺], treat as symptomatic

B. Chronic or Unknown
1. if severe symptoms (seizures or decreased LOC)
   - must partially correct acutely
   - aim for increase of Na⁺ by 1-2 mmol/L/h for 4-6 h
   - limit total rise to 8 mmol/L in 24 h
   - IV 3% NaCl at 1-2 cc/kg/h
   - may need furosemide
2. if asymptomatic
   - water restrict to <1 L/d fluid intake
   - consider IV 0.9% NS + furosemide (reduces urine osmolality, augments excretion of H₂O)
   - consider NaCl tablet or Oxocubes as a source of Na⁺
3. refractory
   - furosemide and oral salt tablets
   - oral urea (osmotic aquarexis)
   - V₂ receptor antagonists (e.g. tolvaptan)
4. always pay attention to patient’s ECF volume status – if already volume-expanded, unlikely to give NaCl; if already volume-depleted, almost never appropriate to give furosemide

C. Options for Treatment of Overly-Rapid Correction
- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2 µg IV)

Impact of IV Solution on Serum [Na⁺]
- formula to estimate the change in serum [Na⁺] caused by retention of 1 L of any infusate
  \[
  \text{change in serum [Na⁺]} = \frac{\text{infusate [Na⁺]} - \text{serum [Na⁺]}}{\text{TBW} + 1 \text{ L}}
  \]
- formula assumes there are no losses of water or electrolytes

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION
1. urine that is inappropriately concentrated for the serum osmolality
2. high urine sodium (>20-40 mmol/L)
3. high FÉ₆₆
Table 5. Disorders Associated with SIADH

Hypernatremia

- hypernatremia: serum [Na⁺] >145 mmol/L
- too little water relative to total body Na⁺; always a hyperosmolar state
- usually due to NET water loss, rarely due to hypertonic Na⁺ gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

Signs and Symptoms
- with acute hypernatremia no time for adaptation, therefore more likely to be symptomatic
- adaptive response: cells import and generate new osmotically active particles to normalize size
- due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

Complications
- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema due to ongoing brain hyperosmolality

Treatment of Hypernatremia
- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na⁺ frequently to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na⁺, but a proportionately larger water loss
- use formula to calculate free water H₂O deficit and replace
- encourage patient to drink pure water, as oral route is preferred for fluid administration
- if unable to replace PO or NG, correct H₂O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl [“2/3 and 1/3”])
- use formula (see Hypernatremia, NP8) to estimate expected change in serum Na⁺ with 1 L infusate
- aim to lower [Na⁺] by no more than 12 mmol/L in 24 h (0.5 mmol/L/h)
- must also provide maintenance fluids and replace ongoing losses
- general rule: give 2 cc/kg/h of free water to correct serum [Na⁺] by about 0.5 mmol/L/h or 12 mmol/L/d

H₂O Deficit and TBW Equations
- TBW = 0.6 x wt (kg) men
- TBW = 0.5 x wt (kg) women
- H₂O deficit = TBW x ([Na⁺]plasma – 140) / 140

Correction of serum [Na⁺] in hypernatremia should not exceed 12 mmol/L/24 h

1 L D5W approximately equals 1 L of free water
1 L 0.45% NS approximately equals 500 mL of free water
DIABETES INSIPIDUS

- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology

- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI: lithium (most common), hypokalemia, hypercalcemia, and congenital

Diagnosis

- urine osmolality inappropriately low in patient with hypernatremia (Uosm <300 mOsm/kg)
- serum vasopressin concentration may be absent or low (central), or elevated (nephrogenic)
- dehydration test: H2O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains <300 (fails to concentrate urine), most likely DI
- administer DDAVP (exogenous ADH) (10 µg intranasally or 2 µg SC or IV)
  • central DI: diagnosed if there is rise in urine osmolality, fall in urine volume
  • treat with DDAVP
  • nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
  • treat with water (IV D5W or PO water), thiazides may help as well (reduced ECF volume stimulates proximal tubular reabsorption of sodium and water, leading to less delivery of glomerular filtrate to ADH sensitive parts of renal tubule, and therefore lower urine volume results)

Potassium Homeostasis

- approximately 98% of total body K⁺ stores are intracellular
- normal serum K⁺ ranges from 3.5-5.0 mEq/L
- in response to K⁺ load, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia
- insulin, catecholamines, and acid-base status influence K⁺ movement into cells
  • aldosterone has a minor effect
- potassium excretion is regulated at the distal nephron
  • K⁺ excretion = urine flow rate x urine [K⁺]

Factors which Increase Renal K⁺ Loss

- hyperkalemia
- increased distal tubular urine flow rate and Na⁺ delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing Na⁺ reabsorption and K⁺ excretion
- metabolic alkalosis (increases K⁺ secretion)
- hypomagnesemia
- increased non-reabsorbable anions in tubule lumen: HCO₃⁻, penicillin, salicylate (increased tubular flow rate increases K⁺ secretion)

Hypokalemia

- serum [K⁺] <3.5 mEq/L

Signs and Symptoms

- usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
- N/V, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
- arrhythmias occur at variable levels of K⁺; more likely if digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum [K⁺]
  • U waves most important (low amplitude wave following a T wave)
  • flattened or inverted T waves
  • depressed ST segment
  • prolongation of Q-T interval
  • with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity

Figure 6. ECG changes in hypokalemia
### Approach to Hypokalemia

1. **emergency measures:** obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of K⁺ as cause of hypokalemia
3. assess contribution of dietary K⁺ intake
4. spot urine K:Cr (should be less than 1 in setting of hypokalemia)
   - if <1 consider GI loss
   - if >1 consider a renal loss
5. consider 24 h K⁺ excretion
6. if renal K⁺ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum [Mg²⁺]

---

### Treatment

- **treat underlying cause**
- if true K⁺ deficit, potassium repletion (decrease in serum [K⁺] of 1 mEq is roughly 100-200 mEq of total body loss)
  - oral sources – food, tablets (K-Dur™), KCl liquid solutions (preferable route if the patient tolerates PO medications)
  - IV – usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
    - max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
  - K⁺-sparring diuretics (triangularerene, spironolactone, amiloride) can prevent renal K⁺ loss
- restore Mg²⁺ if necessary
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- beware of excessive potassium repletion, especially if transcellular shift caused hypokalemia

---

### Hyperkalemia

- **serum [K⁺] >5.0 mEq/L**

### Signs and Symptoms

- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and metabolic acidosis
• ECG changes and cardiotoxicity (do not correlate well with serum [K⁺])
  ▪ peaked and narrow T waves
  ▪ decreased amplitude and eventual loss of P waves
  ▪ prolonged PR interval
  ▪ widening of QRS and eventual merging with T wave (sine-wave pattern)
  ▪ AV block
  ▪ ventricular fibrillation, asystole

**Approach to Hyperkalemia**
1. emergency measures: obtain ECG, if life threatening begin treatment immediately
2. rule out factitious hyperkalemia; repeat blood test
3. hold exogenous K⁺ (PO and IV) and any K⁺ retaining medications
4. assess potential causes of transcellular shift
5. estimate GFR (calculate CrCl using Cockcroft-Gault)

**Treatment**
- acute therapy is warranted if ECG changes are present or if patient is symptomatic
- tailor therapy to severity of increase in [K⁺] and ECG changes
  - [K⁺] <6.5 and normal ECG
    - treat underlying cause, stop K⁺ intake, increase the loss of K⁺ via urine and/or GI tract
  - [K⁺] between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - [K⁺] >7.0 and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. **Protect the Heart**
- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes cardiac toxicity of hyperkalemia, protects cardiac conduction system, no effect on serum [K⁺]
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)
2. Shift K⁺ into Cells
• regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
  ▪ onset of action 15-30 min, lasts 1-2 h
  ▪ monitor capillary blood glucose q1h because of risk of hypoglycemia
  ▪ can repeat every 4-6 h
  ▪ caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
• NaHCO₃ 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO₃ in 1L D5W)
  ▪ onset of action 15-30 min, transient effect, drives K⁺ into cells in exchange for H⁺
  ▪ more effective if patient has metabolic acidosis
• β₂-agonist (Ventolin*) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  ▪ onset of action 30-90 min, stimulates Na⁺/K⁺ ATPase
  ▪ caution if patient has heart disease as may result in tachycardia

3. Enhance K⁺ Removal from Body
• via urine (preferred approach)
  ▪ furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  ▪ fludrocortisone (synthetic mineralocorticoid) if suspect aldosterone deficiency
• via gastrointestinal tract
  ▪ cation-exchange resins: calcium resinium or sodium polystyrene sulfonate (Kayexalate*)
    ▪ increasingly falling out of favour due to risk of colonic necrosis; works by binding Na⁺ in exchange for K⁺, and controversial how much K⁺ is actually removed
    ▪ lactulose PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered - main benefit may be the diarrhea caused by lactulose)
  ▪ Kayexalate* enemas with tap water
• dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

---

**Acid-Base Disorders**

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, and CNS function
- see Respiratory, R6 for more information on respiratory acidosis/alkalosis
- normal concentration of HCO₃⁻ = 24 mEq/L (range: 22-30 mEq/L)
- normal pCO₂ = 40 mmHg (range: 36-44 mmHg)
- each acid base disorder has an appropriate compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)

---

**Figure 9. Approach to acid-base disorders**
**Approach**

1. **Identify the primary disturbance** (see Figure 9)
   - respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

2. **Evaluate compensation. If compensation is not appropriate, a second acid-base disorder is likely present**
   - compensation occurs in the same direction as the primary disturbance

3. **Calculate Plasma AG**
   - \[ AG = [Na^+] - ([HCO_3^-] + [Cl^-]) \]
   - baseline = 12, range 10-14 mEq/L
   - AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin] = 20 g/L, expect AG = 6 mEq/L)

4. **If AG elevated, compare increase in AG with decrease in HCO_3^-**
   - if increase in AG < decrease in HCO_3^-, there is a coexisting non-AG metabolic acidosis
   - if increase in AG > decrease HCO_3^-, there is a coexisting metabolic alkalosis

5. **Calculate Osmolar Gap**
   - osmolar gap = measured osmolality – calculated osmolality
   - calculated osmolality = (2 x [Na^+]) + [urea] + [glucose] (all units are in mmol/L)
   - normal osmolar gap <10
   - if AG >10, consider: methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

---

**Metabolic Acidosis**

**Etiology and Pathophysiology**

1. **Increased AG Metabolic Acidosis (4 types)**
   1. Lactic acidosis (2 types)
      - L-lactic acid
        - Type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
        - Type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain anti-retrovirals, large tumours, mitochondrial myopathies
      - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
        - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility and impaired D-lactate metabolism
   2. Ketoacidosis
      - diabetic
        - starvation
      - alcoholic (decreased carbohydrate intake and vomiting)
   3. Toxins
      - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
      - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
      - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacidosis (salicylate activates fat breakdown)
   4. Advanced renal failure (e.g. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)

2. **Normal AG Metabolic Acidosis (Hyperchloremic Acidosis)**
   1. diarreha (HCO_3^- loss from GI tract)
   2. **RTA**
      - type I RTA (distal): inability to secrete H^+ in collecting duct, leading to impaired excretion of ammonium into urine
      - type II RTA (proximal): impaired HCO_3^- reabsorption
      - type III RTA: combination of Types I and II and is extremely rare
      - type IV RTA: defective ammoniagenesis due to decreased aldosterone, hyporesponsiveness to aldosterone, or hyperkalemia

---

**Causes of Increased Osmolar Gap**
- Methanol
- Ethylene glycol
- Ethanol
- Polyethylene glycol
- Mannitol
- Sorbitol

**Useful Equations**
- AG = [Na^+] - [Cl^-] - [HCO_3^-] (normal range = 10-14 mEq/L)
- Osmolar Gap = measured serum osmolality – calculated osmolality (normal <10 mEq/L)
- “Two Salts and a Sticky BUN”
- Calculated Osmolality = 2[Na^+] + [Urea] + [Glucose] +1.25[Ethanol]

**Causes of Increased AG Metabolic Acidosis**
- **MUDPILES CAT**
  - Methanol
  - Uremia
  - Diabetic ketoacidosis
  - Paraldehyde
  - Isopropyl alcohol/isonicotinamide
  - Indomethacin
  - Lactic acidosis
  - Ethylene glycol
  - Salicylates
  - Cyanide and Carbon monoxide
  - Alcoholic ketoacidosis
  - Toluene
  - or

**KARMEL**
- Ketoacidosis
- ASA
- Renal failure
- Methanol
- Ethylene glycol
- Lactic acidosis

**Causes of Non-AG Metabolic Acidosis**
- **HARDUP**
  - Hyperalimentation
  - Acetazolamide
  - RTA*
  - Diarrhea*
  - Ureteroenteric fistula
  - Pancreaticoduodenal fistula
- *Most common
• to help distinguish renal causes from non-renal causes, use Urine AG = (Na⁺ + K⁺) – Cl⁻  
  - calculation establishes the presence or absence of unmeasured positive ions (e.g. NH₄⁺) in urine  
    - if UAG < 0, suggests adequate NH₄⁺ excretion in urine (likely nonrenal cause: diarrhea)  
    - if UAG > 0, suggests problem is lack of NH₄⁺ in urine (e.g. distal RTA)

**Treatment of Metabolic Acidosis**
1. treat underlying cause  
   - fluid resuscitation insulin for DKA  
   - restore tissue perfusion for Type A lactic acidosis  
   - ethanol/fomepizole +/- dialysis for methanol or ethylene glycol poisoning  
   - alkaline diuresis ± dialysis if ASA overdose
2. correct coexisting disorders of K⁺ (see *Hyperkalemia*, NP13)
3. consider treatment with exogenous alkali (e.g. NaHCO₃) if  
   - severe reduction in [HCO₃⁻] e.g. < 8 mmol/L, especially with very low pH (< 7)  
   - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to HCO₃⁻  
   - note: risks of sodium bicarbonate therapy  
     - hypokalemia: causes K⁺ to shift into cells (correct K⁺ deficit first)  
     - ECF volume overload: Na⁺ load given with NaHCO₃, can exacerbate pulmonary edema  
     - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO₃⁻, and persisting hyperventilation

**Pathophysiology**
• requires initiating event and maintenance factors  
• precipitating factors  
  - GI (vomiting, NG tube) or renal loss of H⁺  
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome  
  - diuretics (contraction alkalosis): decreased excretion of HCO₃⁻, decreased ECF volume, therefore increased [HCO₃⁻]  
  - post-hypercapnia: renal compensation for respiratory acidosis is HCO₃⁻ retention, rapid correction of respiratory disorder results in transient excess of HCO₃⁻  
• maintenance factors  
  - volume depletion: increased proximal reabsorption of NaHCO₃ and increased aldosterone  
  - hyperaldosteronism (1º or 2º): distal Na⁺ reabsorption in exchange for K⁺ and H⁺ excretion leads to HCO₃⁻ generation; aldosterone also promotes hypokalemia  
  - hypokalemia: transcellular K⁺/H⁺ exchange, stimulus for ammoniagenesis and HCO₃⁻ generation

**Metabolic Alkalosis**

![Metabolic alkalosis diagram](image)

**Evaluate Compensation (identify co-existing respiratory acid-base disorders)**
• hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

**Treatment**
• treat underlying cause  
• correct underlying disease, replenish K⁺ and Mg²⁺ deficits, and possibly K⁺-sparking diuretic

**3 Clinical Scenarios that Produce a Mixed Disorder with Near Normal pH**
- Cirrhosis  
- ASA overdose  
- Sepsis

**Figure 10. Approach to metabolic alkalosis**

**Note:** cannot use U₆Cl to assess volume status in presence of alkalemia:  
↑ HCO₃ excretion, drags Na → ↑ Na excretion  
U₆Cl = Urine chloride
Acute Kidney Injury

Definition
- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

Clinical Presentation
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 ml/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

Approach to AKI

Investigations
- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca^{2+}, PO_{4}^{3-}
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- Foley catheterization (rule out bladder outlet obstruction)
- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >4 wk

Treatment
1. preliminary measures
   - prerenal
     - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF)
   - renal
     - address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes

Clues to Prerenal Etiology
- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes
- Increased [urea] >> Increased [Cr]
- Urine [Na+] <10-20 mEq/L
- Urine [Na+] / [Cr] <20 >40
- Urine osmolality >500 <350 mOsm/kg
- Fractional excretion of Na+ <1%

Clues to Renal Etiology
- Appropriate clinical context
- Urinalysis positive for casts:
  - Pigmented granular – ATN
  - WBC – AIN
  - RBC – GN

Clues to Postrenal Etiology
- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis

Drugs Implicated in Prerenal Azotemia
- Diuretics
- NSAIDs
- ACEI/ARBs

Renal transplant is not a therapy for AKI
2. treat complications
   - fluid overload
     - NaCl restriction
     - high dose loop diuretics
   - hyperkalemia (see Approach to Hyperkalemia, NP12)
     - adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporin, tacrolimus, some antibiotics, and chemotherapeutic agents)
   - dialysis

3. definitive therapy depends on etiology

Prognosis
- high morbidity and mortality in patients with sustained AKI and multi-organ failure

Parenchymal Kidney Diseases

Glomerular Diseases

HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

Extent of Changes
- histological term describing the number of glomeruli affected in a given condition:
  - diffuse: majority of glomeruli abnormal
  - focal: some glomeruli affected
- histological term describing the extent to which individual glomeruli are affected in a given condition
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

Types of Changes
- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane
- crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman's space

CLINICAL PRESENTATION OF GLOMERULAR DISEASE

Important Points to Remember
- glomerular diseases have diverse clinical presentations including hematuria, proteinuria, HTN, edema, and decreased GFR
  - each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
    1. asymptomatic urinary abnormalities
       - proteinuria
       - hematuria
    2. nephritic syndrome
       - acute GN
       - rapidly progressive GN
    3. nephrotic syndrome
    4. ESRD

- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum
- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes
PROTEINURIA
- hallmark of nephrotic syndromes
- 24 h urine protein: gold standard to assess degree of proteinuria
- urine ACR: used to screen for diabetic nephropathy
  - microalbuminuria
    - defined as ACR ≥2.8 mg/mmol (female) or ≥2.0 mg/mmol (male)
    - marker of vascular endothelial function
    - an important prognostic marker for kidney disease in DM and HTN (see Diabetes, NP28)
  - microalbuminuria is the earliest sign of diabetic nephropathy
- composition of normal total urine protein
  - upper limit of normal daily excretion of total protein is 150 mg/d
  - upper limit of normal daily excretion of albumin is 30 mg/d
  - the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin light chains or β-2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

Table 8. Daily Excretion of Protein

<table>
<thead>
<tr>
<th>Daily Excretion</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;150 mg total protein (and &lt;30 mg albumin)</td>
<td>Normal</td>
</tr>
<tr>
<td>30-300 mg albumin</td>
<td>Microalbuminuria</td>
</tr>
<tr>
<td>&gt;3500 mg total protein/1.73m² BSA</td>
<td>Nephrotic range proteinuria</td>
</tr>
<tr>
<td>Variable amount of proteinuria</td>
<td>Can be seen with glomerular disease</td>
</tr>
<tr>
<td>Up to 2000 mg per d</td>
<td>Possible tubular disease because of failure to reabsorb filtered proteins</td>
</tr>
</tbody>
</table>
Investigations
- urine R&M, C&S, urea, Cr
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  - CBC, glucose, electrolytes, 24 h urine protein, and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), Hep B, Hep C, HIV, ASOT
- indications for nephrology referral
  - generally, if there is “heavy” proteinuria (ACR >30 mg/mmol), should refer to nephrologist
  - definitely if there is nephrotic syndrome: marked proteinuria >3.5 g/1.73m²/d with hypoalbuminemia (<35 g/L)

HEMaturia
- hallmark of nephritic syndromes
- presence of blood or RBCs in urine
  - gross hematuria: pink, red, or tea-coloured urine
    - in gross hematuria, the urine should be centrifuged
      - if the sediment is red, true hematuria
      - if the supernatant is red, test for heme with a dipstick
        - if supernatant positive for heme: myoglobinuria or hemoglobinuria
        - if negative for heme: pseudohematuria; consider medications (e.g. rifampin), food dyes (e.g. beets), or metabolites (e.g. porphyria)
  - microscopic hematuria: blood in the urine that is invisible to the naked eye, >2-3 RBCs/HPF on microscopy

Figure 14. Approach to red urine

Investigations for Hematuria
- Hx and P/E: family history of nephrolithiasis, hearing loss (Alport’s), cerebral aneurysm (PCKD), diet, recent URTI, irritative and obstructive urinary symptoms (UTI)
- urine R&M, C&S, urea, Cr
- renal U/S
- 24 h urine stone workup if there is a history of stone formation or if there is a stone noted on imaging: calcium, oxalate, citrate, magnesium, uric acid, cysteine
- further workup (if casts and/or proteinuria): CBC, electrolytes, 24 h urine protein and Cr, serology (ANA, RF, C3, C4, p-ANCA, c-ANCA, ASOT)
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age

Glomerular Syndromes

1. ASYMPTOMATIC URINARY ABNORMALITIES

Clinical/Lab Features
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  - isolated proteinuria
    - can be postural
    - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
• hematuria with or without proteinuria
  • IgA nephropathy (Berger’s disease): most common type of primary glomerular disease
    worldwide, usually presents after viral URTI
  • hereditary nephritis (Alport’s disease): X-linked nephritis often associated with
    sensorineural hearing loss; proteinuria <2 g/d
  • thin basement membrane disease: usually autosomal dominant, without proteinuria;
    benign
  • benign recurrent hematuria: hematuria associated with febrile illness, exercise, or
    immunization; a diagnosis of exclusion after other possibilities are ruled out

2. NEPHRITIC SYNDROME

ACUTE NEPHRITIC SYNDROME
• a subset of nephritic syndrome in which the clinical course proceeds over days

Etiology
• etiology can be divided into low and normal complement levels
• frequently immune-mediated, with Ig and C3 deposits found in GBM
• outcome dependent on etiology

Clinical/Lab Features
• proteinuria (but <3.5 g/1.73 m²/d), abrupt onset hematuria (microscopic or macroscopic),
  azotemia (increased Cr and urea), RBC casts and/or dysmorphic RBCs in urine, oliguria, HTN
  (due to salt and water retention), peripheral edema/puffy eyes, smoky urine

RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS/CRESCENTIC GLOMERULONEPHRITIS
• a subset of nephritic syndrome in which the clinical course proceeds over weeks to months
• clinical diagnosis, not histopathological
• any cause of GN can present as RPGN (except minimal change disease)
• additional etiologies seen only as RPGN: Goodpasture’s syndrome and granulomatosis with
  polyangitis (previously called Wegener’s granulomatosis)

Clinical/Lab Features
• fibrous crescents typically present on renal histopathology
• RBC casts and/or dysmorphic RBCs in urine
• classified by immunofluorescence staining
• Type I: Anti-GBM mediated (15% of cases)
• Type II: Immune Complex Mediated (24% of cases)
• Type III: Non-Immune Mediated (60% of cases)
• Type IV: Double Antibody Positive
• treatment: underlying cause for postinfectious; corticosteroids + cyclophosphamide or other
  cytotoxic agent + plasmaphoresis in select cases
• prognosis: 50% recovery with early treatment, depends on underlying cause

3. NEPHROTIC SYNDROME

Clinical/Lab Features
• heavy proteinuria (>3.5 g/1.73 m²/d)
• hypoalbuminemia
• edema
• hyperlipidemia (elevated LDL cholesterol), lipiduria (fatty casts and oval fat bodies on
  microscopy)
• hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
• patient may report frothy urine
• glomerular pathology on renal biopsy
  • minimal change disease (or minimal lesion disease or nil disease) – e.g. glomeruli appear
    normal on light microscopy
  • membranous glomerulopathy
  • focal segmental glomerulosclerosis (FSGS)
  • membranoproliferative GN
  • nodular glomerulosclerosis
• each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause
  proteinuria without obvious glomerular pathology)
### Table 9. Nephrotic Syndrome

### 4. END STAGE RENAL DISEASE

- see *End Stage Renal Disease*, NP35

### INVESTIGATIONS FOR GLOMERULAR DISEASE

- **blood work**
  - first presentation: electrolytes, Cr, urea, albumin, fasting lipids
  - determining etiology: CBC, ESR, serum immunoelectrophoresis, anti-GBM, C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV

- **urinalysis**: RBCs, WBCs, casts, protein
- **24 h urine for protein and CrCl**
- **radiology**
  - CXR (infiltrates, CHF, pleural effusion)
  - renal U/S
- **renal biopsy (percutaneous or open)** if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- **urine immunoelectrophoresis**
  - for Bence-Jones protein if proteinuria present

### SECONDARY CAUSES OF GLOMERULAR DISEASE

**Amyloidosis**
- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary
- secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy

**Systemic Lupus Erythematosus**
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

**Figure 15. Approach to nephritic syndrome**

- Anti-GBM Mediated (RPGN Type I) (15%)
  - Linear IF pattern due to IgG and C3 deposition along capillary loops
  - anti-GBM +ve
  - With lung hemorrhage
    - Goodpasture’s disease
  - Without lung hemorrhage
    - Anti-GBM disease

- Immune Complex Mediated (RPGN Type II) (24%)
  - Granular pattern due to subendothelial or subepithelial deposits of IgG and C3
  - C3 normal
  - IgA nephropathy
    - Henoch-Schönlein purpura
  - Membranoproliferative GN
    - SLE
    - Infective endocarditis
    - Post-infectious GN
    - Cryoglobulinemia

- Non-Immune Mediated (RPGN Type III) (60%)
  - Pauci-immune: no immune staining
  - Decreased C3
  - Membranoproliferative GN
    - c-ANCA +ve
    - Granulomatosis with polyangiitis
  - p-ANCA +ve
    - Churg-Strauss
    - Microscopic polyangiitis

- Double Antibody Positive Disease (RPGN Type IV)
  - Has features of Type I and Type III
  - Double antibody positive
Figure 16. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003

Henoch-Schönlein Purpura
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- glomeruli show varying degrees of mesangial hypercellularity
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

Goodpasture’s Disease
- antibodies against type IV collagen present in lungs and GBM
- more common in 3rd and 6th decades of life, males slightly more affected than females
- present with RPGN type I and hemoptysis/dyspnea
- pulmonary hemorrhage more common in smokers and males
- treat with plasma exchange, cyclophosphamide, prednisone

ANCA-Associated Vasculitis (e.g. Granulomatosis with Polyangiitis and Microscopic Polyangiitis)
- PR3-ANCA (c-ANCA) most commonly associated with the clinical picture of granulomatosis with polyangiitis
- MPO-ANCA (p-ANCA) most commonly associated with the clinical picture of microscopic polyangiitis
- renal involvement very common
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves cyclophosphamide and prednisone

Cryoglobulinemia
- cryoglobulins: monoclonal IgM and polyclonal IgG which precipitate at reduced temperatures
- presents as purpura, fever, Raynaud’s phenomenon, and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

Shunt Nephritis
- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients

HIV-Associated Renal Disease
1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
   - histology: focal and segmental glomerular collapse with mesangial sclerosis; “collapsing FSGS”
   - tubular cystic dilation and tubulo-recticular inclusions
   - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency
   - prognosis: kidney failure within 1 yr without treatment
   - therapy: short-term, high dose steroids, ACEI, HAART
**Infective Endocarditis**
- manifests as mild form of acute nephritic syndrome with decreased serum complement
- *S. aureus* is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

**Hepatitis B**
- can result in membranous nephropathy, polyarteritis nodosa, membranoproliferative GN

**Hepatitis C**
- can result in membranous nephropathy, cryoglobulinemia, and membranoproliferative GN

**Syphilis**
- can result in membranous GN

---

**Tubulointerstitial Disease**

### TUBULOINTERSTITIAL NEPHRITIS

**Definition**
- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

**Signs and Symptoms**
- manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals)
     - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hyperuricosuria
     - proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
     - distal RTA (Type I RTA), usually hypokalemic
     - Na⁺-wasting nephropathy
     - ± hyperkalemia leading to type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
  3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
     - urinary concentrating defect leading to mild nephrogenic DI
     - polyuria

### 1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

**Definition**
- rapid (days to weeks) decline in renal function
- 10-20% of all AKI

**Etiology**
- hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
- infections
- immune
  - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
- idiopathic

**Pathophysiology**
- acute inflammatory cell infiltrates into renal interstitium

**Signs and Symptoms**
- AKI
- if hypersensitivity reaction: may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle (CVA) tenderness
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon
Investigations
- urine
  - mild, non-nephrotic range proteinuria and microscopic hematuria
  - sterile pyuria, WBC casts
  - eosinophils if AIN
- blood work
  - increased Cr and urea
  - eosinophilia if drug reaction
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive

Treatment
- treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

Prognosis
- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely they will have a full renal recovery

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition
- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

Etiology
- persistence or progression of acute TIN
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
  - exogenous
    - analgesics: NSAIDs (common), acetaminophen
    - cisplatin, lithium, cyclosporine, tacrolimus
    - heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
    - Chinese herbs (aristolochic acid)
  - endogenous
    - hypercalcemia, hypokalemia, oxalate, uric acid
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, Sjögren’s, cryoglobulinemia, Goodpasture's, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

Pathophysiology
- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms
- tubular dysfunction (e.g. acidosis, electrolyte disturbances)
- progressive renal failure with azotemia and uremia
- dependent on underlying etiology

Treatment
- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders (Ca^{2+}, PO_{4}^{3-}) and anemia

Findings which Suggest Chronic Tubulointerstitial Nephritis
- normal AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi’s syndrome
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours
3. ACUTE TUBULAR NECROSIS

Definition
- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

Etiology

</tbody>
</table>

Clinical Presentation
- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
- urine: high FE\textsubscript{Na}, pigmented-granular casts

Complications
- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca\textsuperscript{2+}, increased PO\textsubscript{4}\textsuperscript{3-}, hypoalbuminemia

Investigations
- blood work: CBC, electrolytes, Cr, urea, Ca\textsuperscript{2+}, PO\textsubscript{4}\textsuperscript{3-}, blood gases
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
- ECG
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)

Treatment
- largely supportive once underlying problem is corrected
- loop diuretics may help manage volume overload and reduce tubular metabolic requirements to allow for recovery (controversial)
- consider early dialysis in severe/rapidly progressing cases to prevent uremic syndrome

Prevention
- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
  - give N-acetylcysteine 600-1200 mg PO bid day before and day of procedure, give intravenous isotonic fluid (either NaCl or NaHCO\textsubscript{3})
  - isotonic NaHCO\textsubscript{3} at 3 mL/kg over 1 h before procedure and 1 mL/kg/h for 6 h post-procedure if not contraindicated
  - avoid giving diuretics, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency

Meta-Analysis: Effectiveness of Drugs for Preventing Contrast-Induced Nephropathy

Purpose: To determine the effectiveness of N-acetylcysteine, theophylline, fenoldopam, dopamine, kranosmin, furosemide, or mannitol on preventing nephropathy.

Study Selection: RCTs that used these agents in patients receiving iodinated contrast.

Results: In the 41 RCTs included N-acetylcysteine (RR=0.62 [0.44-0.88]) and theophylline (RR=0.49 [0.23-1.06]) reduced the risk of nephropathy more than saline alone. Furosemide increased the risk (RR=3.27 [1.40-7.26]). Other agents did not affect risk of nephropathy.

Conclusion: N-acetylcysteine is more renoprotective than hydration alone.

1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)
   - important, potentially reversible cause of renal failure

Etiology
   - abdominal trauma, surgery, embolism, extra-renal compression, hypercoagulable state, aortic dissection
   - kidney transplant recipients more vulnerable

Signs and Symptoms (depend on presence of collateral circulation)
   - fever, N/V, flank pain
   - leukocytosis, elevated AST, ALP
   - marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
   - acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
   - renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

Investigations
   - renal arteriography (more reliable but risk of atheroembolic renal disease)
   - contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

Treatment
   - prompt localization of occlusion and restoration of blood flow
   - anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
   - medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)
   - chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
   - significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
   - usually associated with large vessel disease elsewhere
   - causes of renal artery stenosis
     - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
     - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
   - when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
   - most common cause of secondary HTN (‘renovascular HTN’), 1-2% of all hypertensive patients
     - etiology
       - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
       - increased angiotensin raises blood pressure in two ways
         1. causes generalized arteriolar constriction
         2. release of aldosterone increases Na⁺ and water retention
     - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

Risk Factors
   - >50 yr
   - smoking
   - other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)
Signs and Symptoms
- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard)

Treatment
- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late (e.g. kidney is already shrunken), however, therapy can be considered to save the opposite kidney if normal

3. RENAL VEIN THROMBOSIS

Etiology
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical presentation determined by rapidity of occlusion and formation of collateral circulation

Signs and Symptoms
- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

Treatment
- thrombolytic therapy ± percutaneous thrombectomy for acute renal vein thrombosis
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

SMALL VESSEL DISEASE

1. HYPERTENSIVE NEPHROSCLEROSIS
- see Hypertension, NP31

2. ATHEROEMBOLIC RENAL DISEASE
- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- investigations
  - eosinophilia, eosinophiluria, and hypocomplementemia
  - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels
- treatment
  - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least one third will develop ESRD
3. THROMBOTIC MICROANGIOPATHY
- see Hematology, H30
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
  - avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY
- cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
  - prerenal azotemia
  - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunsuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

### Analgesic Nephropathies

1. Vasomotor AKI
- clinically: develop prerenal azotemia within a few days of starting NSAID
- normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
- NSAIDs act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
- more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
- treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis
- fenoprofen (60%), ibuprofen, naproxen
- may be associated with minimal change glomerulopathy and nephrotic range proteinuria
- resolves eventually with discontinuation of NSAID, may require interval dialysis
- short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis
- due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
- seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
- papillary necrosis
  - gross hematuria, flank pain, declining renal function
  - calyceal filling defect seen with IVP – "ring sign"
- increased risk of transitional cell carcinoma of renal pelvis
- good prognosis if discontinue analgesics

4. Acute Tubular Necrosis
- can be caused by acetaminophen
  - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
- vascular endothelial damage can also occur
- both direct toxicity and ischemia contribute to the tubular damage
- renal function spontaneously returns to baseline within 1-4 wk
- dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAIDs
- sodium retention (2º to reduced GFR)
- hyperkalemia, HTN (2º to hyporeninemic hypoaldosteronism)
- excess water retention (2º to loss of antagonistic effect of prostaglandins on ADH)
Systemic Disease with Renal Manifestation

Diabetes

- diabetic nephropathy; presence of microalbuminuria or overt nephropathy (e.g. macroalbuminuria) in patients with DM who lack indicators of other renal diseases
- most common cause of end-stage renal failure in North America
- 35-50% of patients with type 1 DM will develop nephropathy, unknown percentage of type 2
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
- indication of possible non-diabetic cause of renal disease in patients with DM
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of systemic disease
  - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
  - family history of non-diabetic renal disease (e.g. PCKD, Alport’s)

DIABETIC RENAL COMPLICATIONS

1. Progressive Glomerulosclerosis
   - classic diabetic glomerular lesion; Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
   - more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix
   - Stage 1: Normal GFR
   - Stage 2: Detectable microalbuminuria (0-300 mg/24 h)
   - Stage 3: Macroalbuminuria (>300 mg/24 h)
   - Stage 4: Proteinuria (>500 mg/24 h)

2. Accelerated Atherosclerosis
   - common finding
   - may increase angiotensin II production resulting in increased BP
   - increased risk of ATN secondary to contrast media

3. Autonomic Neuropathy
   - affects bladder leading to functional obstruction and urinary retention
   - residual urine promotes infection
   - obstructive nephropathy

4. Papillary Necrosis
   - type 1 DM susceptible to ischemic necrosis of medullary papillae
   - sloughed papillae may obstruct ureter
   - can present as renal colic or with obstructive features ± hydroureteronephrosis

Figure 18. GFR and urine protein over time in DM

Protein Restriction for Diabetic Renal Disease
Cochrane DB Syst Rev 2007;4:CD002181

Purpose: To review the effects of dietary protein restriction on the progression of diabetic nephropathy.

Study Selection: RCTs and before and after studies of the effects of restricted protein diet on renal function in subjects with DM. 12 studies were reviewed.

Results: The risk of end-stage renal disease or death was lower in patients on low-protein diet. In patients with type 1 DM no effect on GFR was noted in the low-protein diet group.

Renoprotective Effect of Angiotensin-Receptor Antagonist Ibesartan in Patients with Nephropathy Due to Type 2 DM
NEJM 2001;345:851-860

Study: Multicentre, RCT, mean follow-up of 2.6 yr.

Patients: 808 patients (mean age 70 yr) with type 2 DM, HTN, and nephropathy (<24 h proteinuria >800 mg, serum Cr 09-265 umol/L, male), serum Cr 106-265 umol/L (female).

Intervention: BP control with Ibesartan vs. amiodipine vs. placebo, with use of adjuncts (not including ACEIs, ARBs, or CCB) as needed.

Outcomes: Primary composite endpoint included doubling of serum Cr, ESRD, or death. Secondary composite endpoint included morbidity and mortality from CVD causes.

Results: BP control was similar in all three arms. Ibesartan had a relative risk reduction of 25% vs. placebo and 23% vs. amiodipine for the primary end point. The Ibesartan group had a 3% risk reduction vs. placebo and 37% reduction vs. amiodipine for risk of doubling serum Cr. Serum Cr increased more slowly in the Ibesartan group versus placebo or amiodipine. No difference in absolute mortality or secondary end point.

Conclusion: Ibesartan conferred significant renoprotective benefits in patients with type 2 DM and nephropathy, independent of blood pressure lowering effects.
2013 Canadian Diabetes Association Clinical Practice Guidelines on Chronic Kidney Disease in Diabetes

- screen for microalbuminuria with a random urine test for albumin to Cr ratio (ACR) and eGFR with a serum Cr (e.g. using MDRD equation)
  - type 1 DM: annually in post-pubertal individuals after 5 yr of diagnosis
  - type 2 DM: at diagnosis, then annually
- If eGFR >60 mL/min or ACR <2.0 mg/mmol: there is no CKD, re-screen in 1 yr
- If urine ACR >20.0 mg/mmol: diagnose CKD
- If ACR <2.0 mg/mmol but >2.0 mg/mmol: order serum Cr for eGFR in 3 mo and 2 repeats of random urine ACRs over the next 3 mo; at 3 mo: if eGFR ≤60 mL/min or if >2/3 ACRs are >2.0 mg/mmol, diagnose CKD
- If CKD diagnosed, ordered urine R+M and dipstick, if negative then diagnose CKD in DM with CKD in DM: urine ACR and serum Cr (for eGFR) every 6 mo
- delay screening if transient cause of albuminuria or low eGFR
- evaluate for other causes of proteinuria, rule out non-diabetic renal disease
- avoid unnecessary potential nephrotoxins (NSAIDs, aminoglycosides, dye studies)

Priorities in the Management of Patients with DM

1. vascular protection for all patients with DM
   - ACEI, antiplatelet therapy (as indicated)
   - BP control, glycemic control, lifestyle modification, lipid control
2. optimization of BP in patients who are hypertensive
   - treat according to HTN guidelines
3. renal protection for DM patients with nephropathy (even in absence of HTN)
   - type 1 DM: ACEI
   - type 2 DM: CrCl >60 mL/min: ACEI or ARB; CrCl <60 mL/min: ARB
   - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
   - combination of ACEI and ARB not recommended for proteinuria
   - check serum Cr and K+ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
   - serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
   - if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
   - consider holding ACEI, ARB, and/or diuretic with acute illness and in women before becoming pregnant
   - consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets, or unable to stay on ACEI or ARB

Scleroderma

- see Rheumatology, RH13
- 50% of scleroderma patients have renal involvement (mild proteinuria, high Cr, HTN)
- renal involvement usually occurs early in the course of illness
- histology: media thickened, “onion skin” hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% of scleroderma patients have a “scleroderma renal crisis” (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- treatment: BP control with ACEI slows progression of renal disease

Multiple Myeloma

- see Hematology, H49
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy or “myeloma kidney”
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease
  - diffuse tubular obstruction
  - light chain cast nephropathy
- large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
- proteinuria and renal insufficiency, can progress rapidly to kidney failure

References

-imen, J.; et al. The need for dialysis and early death among patients with renal crisis. Results: 61% of patients with renal crisis had good outcomes (95 had no dialysis and 24 received temporary dialysis), only 4 of these patients progressed to chronic renal failure and permanent dialysis. Greater than 50% of the patients who initially required dialysis discontinued it 5-18 mo later. Permanent dialysis or early death occurred in 39% of the patients.
-Conclusion: Renal crisis can be managed when HTN is aggressively controlled with ACEI.
• monoclonal Ig deposition disease
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
• lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
• poor candidates for kidney transplantation

**Malignancy**

• cancer can have many different renal manifestations
• kidney transplantation cannot be performed unless malignancy is cured
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin’s) or membranous GN (non-Hodgkin’s)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/mets: postrenal failure secondary to obstruction
  - 2’ amyloidosis
  - radiotherapy (radiation nephritis)

**Chronic Kidney Disease**

**Definition**

• progressive and irreversible loss of kidney function
• abnormal markers (Cr, urea)
  - GFR <60 mL/min for >3 mo; or
  - kidney pathology seen on biopsy; or
  - decreased renal size on U/S (kidneys <9 cm)

**Clinical Features**

• volume overload and HTN
• electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
• uremia

</tbody>
</table>

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year

“D” is added to G5 for patients requiring dialysis

Classification is based on cause, GFR, and amount of albuminuria

Rate of progression and risk of complications are determined by the cause of CKD

**Management of Chronic Kidney Disease**

• diet
  - preventing HTN and volume overload
  - Na+ and water restriction
  - preventing electrolyte imbalances
  - K+ restriction (40 mmol/d)
  - PO43- restriction (1 g/d)
  - avoid extra–dietary Mg2+ (e.g. antacids)
  - preventing uremia and potentially delaying decline in GFR
  - protein restriction with adequate caloric intake in order to limit endogenous protein catabolism
• medical
  ▪ adjust dosages of renally excreted medications
  ▪ HTN: ACEI (target 130/80 or less), loop diuretics when GFR <25 mL/min
  ▪ dyslipidemia: statins
  ▪ calcium and phosphate disorders
    ▪ calcium supplements (e.g. TUMS®) treats hypocalcemia when given between meals and binds phosphate when given with meals
    ▪ consider calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic
    ▪ sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
    ▪ vitamin D analogues are being introduced in the near future
    ▪ cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca\textsuperscript{2+}, decreasing PTH)
  ▪ metabolic acidosis: sodium bicarbonate
  ▪ anemia: erythropoietin injections (hematocrit <30%); target hematocrit 33-36%
  ▪ clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
• dialysis (hemodialysis, peritoneal dialysis)
• renal transplantation

Prevention of Progression
• as above
• control of HTN, DM, cardiovascular risk factors (e.g. smoking cessation)
• avoid nephrotoxins
• address reversible causes of AKI

**Hypertension**

• see Family Medicine, FM35
• HTN occurs in about 20% of population
• etiology classified as primary ("essential"; makes up 90% of cases) or secondary
• primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
• secondary HTN can be caused by renal parenchymal or renal vascular disease

**Hypertensive Nephrosclerosis**

**Renovascular Hypertension**

• see Vascular Diseases of the Kidney, NP27

**Renal Parenchymal Hypertension**

• HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
• mechanism of HTN not fully understood but may include
  ▪ excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  ▪ production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  ▪ ineffective sodium excretion with fluid overload

---

Effects of Lowering LDL Cholesterol with Simvastatin and Ezetimibe in Patients with Chronic Kidney Disease

*Lancet* 2011;377:2181-2192

**Purpose:** To assess the efficacy and safety of the combination of simvastatin and ezetimibe in patients with moderate to severe CKD.

**Study:** Randomized, double-blind trial with 9,270 patients with CKD with no known history of myocardial infarction or coronary vascularization.

Patients were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo.

**Primary Outcome:** First major atherosclerotic event (non-fatal myocardial infarction or coronary death, non-hemorrhagic stroke, or any arterial revascularization procedure).

**Results:** The simvastatin plus ezetimibe group was associated with an average LDL cholesterol difference of 0.85 mmol/L during a median follow-up of 4.9 yr. There was a 17% proportional reduction in major atherosclerotic events in the simvastatin plus ezetimibe group compared to placebo.

**Conclusions:** Reducing LDL cholesterol with a treatment regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with moderate to severe CKD.
Investigations
- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of CrCl and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy

Treatment
- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na+ restriction (2g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K+ and Cr) if there is significant proteinuria (>300 mg/d)

Cystic Diseases of the Kidney
- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

Adult Polycystic Kidney Disease
- autosomal dominant; at least 2 genes: \textit{PKD1} (chr 16p) and \textit{PKD2} (chr 4q)
- \textit{PKD1} (1:400), \textit{PKD2} (1:1,000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant polycystin gene but accumulate a series of second somatic hits precipitating the condition
- \textit{PKD1} encodes a protein that is responsible for cell-cell and cell-matrix interaction and sensing fluid flow by associating with cilia
- \textit{PKD2} encodes a protein that is a Ca\textsuperscript{2+} permeable nonselective cation channel that associates with cilia and is thought to control intracellular Ca\textsuperscript{2+} in response to flow
- defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth
- most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), cerebral aneurysm (10%), diverticulosis
- polycystic liver disease rarely causes liver failure
- less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

Signs and Symptoms
- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain
- hematuria (microscopic frequently initial sign, gross)
- nocturia (urinary concentrating defect)
- rarely extra-renal presentation (e.g. erupted berry aneurysm, diverticulitis)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

Common Complications
- urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course
- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations
- radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- gene linkage analysis for \textit{PKD1} for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)
Treatment
- goal: to preserve renal function by prevention and treatment of complications
- educate patient and family about disease, its manifestations, and inheritance pattern
- genetic counselling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat HTN with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy to create room for renal transplant

Medullary Sponge Kidney
- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern (“bouquet of flowers”), “Swiss cheese” appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

Autosomal Recessive Polycystic Kidney Disease
- 1:20,000 incidence
- prenatal diagnosis by enlarged kidneys
- perinatal death from respiratory failure
- patients who survive perinatal period develop CHF, HTN, CKD
- treated with kidney and/or liver transplant

End Stage Renal Disease
- ESRD represents a decline in kidney function requiring renal replacement therapy which can occur over days to weeks (AKI), over months to years (CKD), or as a combination of the two

Presentation of End Stage Renal Disease
1. Volume Overload
   - due to increase in total body Na⁺ content
   - signs: weight gain, HTN, pulmonary or peripheral edema
2. Electrolyte Abnormalities
   - high
     - K⁺ (decreased renal excretion, increased tissue breakdown)
     - PO₄³⁻ (decreased renal excretion, increased tissue breakdown)
     - Ca²⁺ (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
     - uric acid
   - low
     - Na⁺ (failure to excrete excessive water intake)
     - Ca²⁺ (decreased Vitamin D activation, hyperphosphatemia, hypoalbuminemia)
     - HCO₃⁻ (especially with sepsis or severe heart failure)
3. Uremic Syndrome
   - manifestations result from retention of urea and other metabolites as well as hormone deficiencies
Figure 19. Signs and symptoms of end stage renal disease

Complications
- CNS: decreased LOC, stupor, seizure
- CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
  - endocrine
    - decreased testosterone, estrogen, progesterone
    - increased FSH, LH
  - metabolic
    - renal osteodystrophy: secondary increased PTH due to decreased Ca^{2+}, high PO_{4}^{3-}, and low active vitamin D
    - osteitis fibrosa cystica
    - hypertriglyceridemia, accelerated atherogenesis
    - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hemoptoma, calciphylaxis (vascular Ca^{2+} deposition)
Renal Replacement Therapy

Dialysis

*Unresponsive to medications

• hemodialysis: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  • available as intermittent (e.g. 3x/wk), continuous (CVVHD) or sustained low efficiency (SLED)
  • can be delivered at home or in-centre, nocturnal
  • vascular access can be achieved through a central line, an artificial graft, or an AV fistula
• patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 µmol/L, or within 1 yr of an anticipated need
• peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  • advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  • available as continuous ambulatory (CAPD; four exchanges per day) or cyclic (CCPD; machine carries out exchanges overnight)
• refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

When to Initiate Dialysis

CrCl <20 mL/min
• Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula
CrCl <15 mL/min
• Weigh risk and benefits for initiating dialysis
CrCl <10 mL/min
• Dialysis should be initiated

NOTE
• Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
• Monitor for uremic complications
• Significant benefits in quality of life can occur if dialysis started before CrCl <15 mL/min
• It is unclear whether patients who start dialysis early have increased survival
• A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Commonly Used Immunosuppressive Drugs

Calcineurin inhibitors
• Cyclosporine
• Tacrolimus

Antiproliferative medications
• Mycophenolate mofetil
• Azathioprine

Other agents
• Sirolimus
• Prednisone

Anti-lymphocyte antibodies
• Thymoglobin
• Basiliximab
**Renal Transplantation**

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
  - best way to reverse uremic signs and symptoms
  - only therapy shown to improve survival in CKD patients with ESRD
- native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- 1 yr renal allograft survival rates ≥90%

**Complications**
- acute rejection: graft site tenderness, rise in Cr, oliguria, ± fever, although symptoms are uncommon
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- #1 cause of mortality in transplanted patients is cardiovascular disease
- immunosuppressant drug therapy: side effects include infections, malignancy (skin, Kaposi's sarcoma, post-transplant lymphoproliferative disorder)
- *de novo* GN (usually membranous)
- new-onset DM (often due to prednisone use)
- cyclosporine or tacrolimus nephropathy (see *Small Vessel Disease*, NP18)
- chronic allograft nephopathy
  - early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
  - immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
  - transplant glomerulopathy from antibody injury causes nephrotic proteinuria
- CMV (cytomegalovirus) infection and other opportunistic infections usually occur between 1 and 6 mo post-transplant
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss

## Landmark Nephrology Trials

<table>
<thead>
<tr>
<th>Trial</th>
<th>Reference</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>4D</td>
<td>NEJM 2005; 353:238-48</td>
<td>Patients with type 2 DM receiving maintenance hemodialysis were randomized to 20 mg of atorvastatin per day or matching placebo; no difference in composite index of death from cardiac causes, nonfatal myocardial infarction, and stroke</td>
</tr>
<tr>
<td>AASK</td>
<td>JAMA 2001; 285:2719-28</td>
<td>Ramipril, compared with amldopine, slows progression of hypertensive renal disease and proteinuria and may benefit patients without proteinuria as well</td>
</tr>
<tr>
<td>ACCOMPLISH</td>
<td>NEJM 2008; 359:2417-28</td>
<td>Combination treatment with an ACEI and a CCB (benazepril-amldopine) was more successful than a combination of ACEI and a thiazide diuretic (benzapril-HCTZ) in reducing cardiovascular events in patients with HTN who were at risk for such events</td>
</tr>
<tr>
<td>ACEI and Diabetic</td>
<td>NEJM 1993; 329:1456-62</td>
<td>Captopril protects against deterioration in renal function in insulin-dependent diabetic nephropathy and is significantly more effective than blood pressure control alone</td>
</tr>
<tr>
<td>ALERT</td>
<td>Lancet 2003; 361:2024-31</td>
<td>The use of fluvastatin in renal transplant recipients did not significantly decrease the risk of the occurrence of a major adverse cardiac event (defined as cardiac death, non-fatal MI, or coronary intervention procedure) compared with placebo; however, there was a significant reduction in cardiac deaths or non-fatal MI</td>
</tr>
<tr>
<td>ALTITUDE</td>
<td>Early Termination (Unpublished Results; protocol – ADT 2009; 24:1663-171)</td>
<td>Combining Aliskiren with ACEI or ARB in high-risk patients with type 2 DM leads to increased incidence of nonfatal stroke, hyperkalemia, and hypertension</td>
</tr>
<tr>
<td>ASTRAL</td>
<td>NEJM 2009; 361:1953-62</td>
<td>Renal artery revascularization compared to medical therapy does not improve renal function, BP, renal or cardiovascular events, or mortality, and carries significant operative risks</td>
</tr>
<tr>
<td>AURORA</td>
<td>NEJM 2009; 360:1395-407</td>
<td>Patients receiving maintenance hemodialysis randomized to rosuvastatin 10 mg daily or placebo; rosuvastatin lowered the LDL cholesterol level but had no significant effect on the composite primary end point of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke</td>
</tr>
<tr>
<td>BENEDICT</td>
<td>NEJM 2004; 351:1941-51</td>
<td>Treatment with ACEI trandolapril alone or trandolapril combined with verapamil decreased the incidence of microalbuminuria in patients with type 2 DM and HTN with normoalbuminuria</td>
</tr>
<tr>
<td>CHOIR</td>
<td>NEJM 2006; 355:2085-98</td>
<td>Patients with CKD were randomly assigned to receive a dose of epoetin alfa targeted to achieve a hemoglobin level of 135 g/L or 113 g/L; the higher target group had an increased risk of death, myocardial infarction, hospitalization for congestive heart failure (without renal replacement therapy), or stroke</td>
</tr>
<tr>
<td>CORAL</td>
<td>NEJM 2014; 370:13-22</td>
<td>Renal-artery stenting did not confer a significant benefit with respect to the prevention of renal or cardiac events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease</td>
</tr>
<tr>
<td>CREATE</td>
<td>NEJM 2006; 355:2071-84</td>
<td>Patients with CKD (15-35 mL/min) and mild to moderate anemia (110-125 g/L) were randomized to normal (130-150 g/L) or sub-normal (105-115 g/L) hemoglobin levels; early and complete correction of hemoglobin did not reduce the risk of cardiovascular events</td>
</tr>
<tr>
<td>DETAIL</td>
<td>NEJM 2004; 351:1952-61</td>
<td>The ARB telmisartan and the ACEI enalapril are equally effective in slowing renal function deterioration in type 2 DM with mild to moderate HTN and early nephropathy</td>
</tr>
<tr>
<td>ELITE-SYMPHONY</td>
<td>NEJM 2007; 357:2562-75</td>
<td>Daclizumab induction, MMF, steroids, and low-dose tacrolimus effectively maintain stable renal function following renal transplantation, without the negative effects on renal function commonly reported for standard CNI regimens</td>
</tr>
<tr>
<td>FHN</td>
<td>NEJM 2010;363:2287-300</td>
<td>Patients were randomized to dialysis 6x/wk (frequent) or 3x/wk (conventional); frequent hemodialysis was associated with improvement in composite outcomes of death, or change in left ventricular mass and death, or change in a physical-health composite score; frequent hemodialysis caused more frequent interventions related to vascular access</td>
</tr>
<tr>
<td>HEMO</td>
<td>NEJM 2002; 344:1907-17</td>
<td>Use of high dose dialysis or high flux membranes versus standard dose or low flux in thrice-weekly dialysis does not improve survival or outcomes; possible benefit in cardiac-related outcomes with high flux membranes</td>
</tr>
<tr>
<td>IDEAL</td>
<td>NEJM 2010; 363:609-19</td>
<td>Patients with progressive CKD and GFR between 10 and 15 mL/min randomized to initiate dialysis at GFR of 10-14 mL/min (early) or 5-7 mL/min (late); early initiation of dialysis in patients with stage G5 CKD was not associated with an improvement in survival or clinical outcomes</td>
</tr>
<tr>
<td>IDNT</td>
<td>NEJM 2001; 345:851-60</td>
<td>Treatment with ibrsartan reduced the risk of developing end-stage renal disease and worsening renal function in patients with type 2 DM and diabetic nephropathy</td>
</tr>
<tr>
<td>IRMA</td>
<td>NEJM 2001; 345:870-8</td>
<td>Ibrsartan is renoprotective independently of its blood pressure lowering effect in patients with type 2 DM and microalbuminuria</td>
</tr>
<tr>
<td>MDRD</td>
<td>Ann Intern Med 1995; 123:754-62</td>
<td>Patients with proteinuria of more than 1 g/d should have a target BP &lt;125/75 mmHg; patients with proteinuria of 0.25 to 1.0 g/d should have a target BP &lt;130/80 mmHg</td>
</tr>
<tr>
<td>ONTARGET</td>
<td>Lancet 2008; 372:547-53</td>
<td>Telmisartan and ramipril monotherapy reduced proteinuria and rise in Cr in patients with high vascular risk; combination of the two agents led to increased acute renal failure episodes, syncope, and hypotension</td>
</tr>
<tr>
<td>REIN</td>
<td>Lancet 1999; 354:359-64</td>
<td>In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria</td>
</tr>
<tr>
<td>REIN2</td>
<td>Lancet 2005; 365:939-46</td>
<td>In non-diabetic nephropathy already on ACEI, no further benefit from intensified BP control (sBP/dBP&lt;130/80 mmHg) by adding a CCB versus conventional BP control (dBP&lt; 90 mmHg) on ACEI alone</td>
</tr>
<tr>
<td>RENAAAL</td>
<td>NEJM 2001; 345:861-9</td>
<td>Losartan conferred significant renal benefits in patients with type 2 DM and nephropathy and was generally well-tolerated</td>
</tr>
<tr>
<td>RENAL</td>
<td>NEJM 2009; 361:1627-38</td>
<td>High intensity continuous renal-replacement therapy in AKI does not improve survival or outcomes compared to low intensity treatment, and is associated with higher rates of hypophosphatemia</td>
</tr>
<tr>
<td>Trial</td>
<td>Reference</td>
<td>Results</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Rituximab in ADPKD</td>
<td>NEJM 2012; 367:2407-18</td>
<td>Tolupratin (vs. placebo) slowed the increase in total kidney volume and decline in kidney function over a 3-year period in patients with ADPKD but was associated with a higher discontinuation rate, due to adverse events</td>
</tr>
<tr>
<td>ROAD</td>
<td>JASN 2007; 18:1889-98</td>
<td>Uptitration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency</td>
</tr>
<tr>
<td>ROADMAP</td>
<td>NEJM 2011; 364:907-17</td>
<td>The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with type 2 DM, normoalbuminuria, and good blood pressure control; however, a higher rate of fatal cardiovascular events was found amongst patients with preexisting coronary heart disease in the olmesartan group</td>
</tr>
<tr>
<td>SHARP</td>
<td>Lancet 2011; 377:2181-92</td>
<td>Randomized placebo-controlled trial in patients with CKD and no history of MI or coronary revascularization took simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo; simvastatin 20 mg plus ezetimibe 10 mg daily resulted in reduction of LDL cholesterol with associated reduction of major atherosclerotic events in patients with CKD</td>
</tr>
<tr>
<td>TREAT</td>
<td>NEJM 2009; 361:2019-32</td>
<td>Patients with type 2 DM, CKD, and anemia were randomized to darbepoetin targeting a hemoglobin of 13 g/dL or placebo; darbepoetin did not reduce the risk of death, a cardiovascular event, or a renal event, and was associated with an increased risk of stroke</td>
</tr>
</tbody>
</table>

Approach to the Neurological Complaint

• Two questions: Where is the lesion? What is the lesion?

Lesion Localization

• cortical
  • contralateral paresis (with differential effect on face and arm vs leg)
  • UMN injury (normal tone, hyperreflexia, Babinski sign, spasticity, no atrophy)
  • homonymous hemianopia midline
  • cortical sensory loss (hemisensory loss, position sense, two-point discrimination, graphesthesia, stereognosis)
  • dominant hemisphere (aphasia, alexia, agraphia, acalculia, left-right disorientation)
  • non-dominant hemisphere syndromes (hemineglect, dysprosody, amusia, constructional apraxia)
  • homonymous hemianopia/quadrantanopia
  • gaze deviation (eyes look toward infarct side of the lesion)
  • partial seizure
  • agnosia (visual, auditory)
  • apraxia
  • dominant hemisphere (aphasia, syndromes (alexia, without agraphia, acalculia, Gerstmann syndrome)
  • non-dominant hemisphere syndromes (denial, hemineglect, constructional apraxia)
  • alien hand syndrome

• subcortical white matter:
  • internal capsule: contralateral paresis with equal face, arm, leg involvement without sensory/cortical deficits; contralateral dysmetria/clumsiness and leg paresis
  • basal ganglia: pill-rolling tremor, bradykinesia, festinating gait, hemiballismus, chorea, dystonic posture (basal ganglia)
  • thalamus: dense sensory loss (thalamic), contralateral severe pain

• brainstem: (bulbar)
  • cranial nerve deficits
  • crossed hemiplegia or sensory loss (i.e. ipsilateral face, contralateral body)
  • crossed sensory loss
  • dysmetria
  • ipsilateral cerebellar (rapid alternating movements, tandem gait)
  • nystagmus toward lesion, diplopia, INO (impaired adduction on contralateral gaze)
  • dysphagia
  • dysarthria (impaired speech articulation)
  • hearing loss
  • vertigo

• cerebellum
  • ipsilateral ataxia (unsteadiness, incoordination)
  • dysmetria
  • intention tremor
  • dysdiadochokinesia
  • wide-based gait, truncal titubation (staggers, reeling, lurching)
  • scanning speech (explosive speech with noticeable pauses and accentuated syllables)
  • nystagmus, distorted smooth pursuit, oscillopsia
• spinal cord
  ▪ absence of facial involvement with bilateral motor and/or sensory deficits below the lesion without facial involvement
  ▪ sphincter dysfunction
  ▪ ataxia, sensory level (sharp line below which there is decreased sensation); sensory deficits exist; suspended "cape-like" sensory level
  ▪ LMN signs (flaccid paresis, hypotonia, hyporeflexia, atrophy, fasciculations) at level of lesion; UMN signs below lesion (marked spasticity and Babinski)
  ▪ bowel, bladder incontinence, sexual dysfunction
  ▪ saddle anesthesia
  ▪ ataxia
  ▪ cord compression symptoms

• nerve root
  ▪ multiple peripheral nerve involvement
  ▪ radiculomyotomal/dermatomal deficits
  ▪ radiating back/neck pain

• peripheral nerve
  ▪ distal "stocking-glove distribution" sensory loss
  ▪ distal paresis
  ▪ LMN signs (hypotonia, hyporeflexia, fasciculations, atrophy)

• neuromuscular junction
  ▪ fluctuating ocular and proximal muscle weakness
  ▪ fatigable upgaze and diplopia
  ▪ bulbar involvement (bulbar symptoms)
  ▪ dysphonia, dysarthria

• muscle
  ▪ symmetric proximal weakness without sensory deficits +/-(climbing stairs, up from chair, combing hair)
  ▪ muscle tenderness
  ▪ muscle atrophy

### Differential Diagnosis

- vascular: ischemia, hemorrhage, vasculitis (temporal arteritis), aneurysm, vasospasm, hemato logic, embolic, thrombotic
- infectious/post-infectious: meningitis, encephalitis, sinus, osteomyelitis, abscess; viral, (herpes simplex, HIV, JC, polio, rabies), bacterial, (meningococcal, Lyme, botulism), mycobacterial (TB), spirochete (syphilis), parasitic, (cytisocercosis), protozoal, mycobacterial, (malaria), fungal, spirochete, (histoplasmosis, cryptococcus), prion, (CJD), post-infectious (GBS)
- neoplastic/paraneoplastic: metastatic (breast, lung, kidney, lymphoma, melanoma, kidney, breast) or primary (glioblastoma multiforme, meningioma, schwannoma, primary CNS lymphoma)
- paraneoplastic: small cell lung carcinoma, testicular, breast, gastrointestinal, ovarian
- degenerative: AD, ALS, FTD, HD, PD, PSP
- demyelinating: MS, GBS
- drugs: Alzheimer's, Parkinson's, ALS, medications/drugs, (anticholinergics, opiates, sedatives, chemotherapy), substance use/exposure (stimulants, hallucinogens, EtOH, heavy metals, carbon monoxide), withdrawal, pernicious anemia (levodopa, benzodiazepine)
- deficiencies: thiamine, niacin, pyridoxine (B6), vitamin B12, vitamin D, vitamin E
- inflammatory/auto-immune: polymyositis, myasthenia gravis, GBS, MS, dermatomyositis, MG, post-radiation therapy, granulomatous, collagen vascular, auto-immune
- ictal: epilepsy
- congenital/hereditary: hydrocephalus, cerebral palsy, fragile X syndrome
- anatomic/structural: ICP, cauda equina syndrome, herniation, HTN, decreased pressure (tonsillar, disc), Arnold-Chiari malformation, space-occupying lesion: tumour, pus, blood
- autoimmune
- traumatic: concussion, vertebral fracture, SDH, SAH, epidural hemorrhage
- endocrine/metabolic: DM, cirrhosis, hypoglycemia, uremia, hepatic encephalopathy, hypercapnia, thyroid, electrolyte, liver function test abnormality, endocrine, enzyme defect/ deposition (lysosomal and other), (Na⁺, K⁺, Ca²⁺, Mg²⁺), mitochondrial, nutrient deficiency
- toxic: medications/drugs, toxins, withdrawal
- movement disorder (dystonia, dyskinesia)
- sleep disorder
- ictal
- sleep: obstructive sleep apnea, restless leg syndrome, narcolepsy
- psychiatric
- psychiatric: depression, schizophrenia, anxiety, psychosomatic, malingering, pseudoseizure
- idiopathic
The Neurological Exam

General Exam and Mental Status

- **vitals:** pulse (especially rhythm), BP, RR, temperature
- **H&N:** meninges, head injury/bruises (signs of basal skull fracture: Battle’s sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
- **CVS:** carotid bruises, heart murmurs
- **mental status:** orientation (person, place, time), LOC (GCS) (see Emergency Medicine, ER4)
  - GCS/15 – Motor/6, Verbal/5 (T= intubated), Eyes/4
- **cognition**
  - Folstein MMSE – /30 (note: dementia is a clinical diagnosis and is not diagnosed by cognitive testing)
  - MoCA – /30 (≥26 is considered normal)
  - frontal lobe testing (for perseveration)
  - clock drawing

Cranial Nerve Exam

- **olfactory (CN I):** odour sensation (test each nostril separately)
- **optic (CN II)**
  1. visual acuity: test each eye individually using best corrected vision
  2. visual fields by confrontation
  3. pupil: direct and consensual pupillary reaction (affecter limb), accommodation, swinging flashlight test (see Relative Afferent Pupillary Defect, Ophthalmology; OP33)
  4. fundoscopy: optic disc edema, optic disc pallor, venous pulsations, hemorrhages
- **oculomotor (CN III), trochlear (CN IV), and abducens (CN VI)**
  1. oculomotor (CN III): levator palpebrae superioris, medial rectus, superior rectus, inferior rectus, inferior oblique, efferent limb of pupillary light response
  2. trochlear (CN IV): superior oblique
  3. abducens (CN VI): lateral rectus
- **trigeminal (CN V)**
  1. sensory: V1 (above supraorbital ridge), V2 (buccal area), V3 (mandible), corneal reflex (affecter)
  2. motor: temporalis, masseter, pterygoids, jaw jerk reflex
- **facial (CN VII)**
  1. inspect for facial asymmetry, widening of palpebral fissure, flattened nasolabial fold, drooping mouth, and involuntary facial movements
  2. sensorimotor: muscles of facial expression, hyperacusis (stapedius), corneal reflex (efferent)
  3. visceral sensory: taste of anterior 2/3 of tongue
  4. visceral motor: salivary and lacrimal glands
- **vestibulocochlear (CN VIII)**
  1. vestibular: nystagmus, caloric reflexes
  2. cochlear: whisper, Rinne, Weber
- **glossopharyngeal (CN IX) and vagus (CN X):** palatal elevation, gag reflex, vocal cord function, swallowing, taste of posterior third of tongue
- **accessory (CN XI):** trapezius and sternocleidomastoid strength
- **hypoglossal (CN XII):** tongue muscle bulk, fasciculations, strength

Motor Exam

- **bulk:** atrophy, asymmetry
- **tone:** hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling
- **power:** pronator drift, asymmetric forearm rolling test
- **reflexes:** deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski, Hoffmann, clonus
- **abnormal movements:** tremors, chorea, dystonia, dyskinesia, hemiballism, myoclonus, athetosis, tics, fasciculations
- **abnormal posturing:** decorticate (flexion upper extremities, extension lower extremities), decerebrate (extension)

See Online Atlas for Cranial Nerves Exam, Motor Exam, and Sensory Exam Techniques

Battle’s sign = mastoid ecchymosis
Raccoon eyes = periorbital ecchymosis
If patient has not brought their glasses, have them look through a pinhole for best corrected vision
When testing CN I, avoid noxious smells like ammonia, as this tests CN V
Screening Neurologic Exam
- mental status: orientation (person, place, time), obeys commands, GCS
- head and neck: examine for lacerations, contusions, deformities, signs of basal skull fracture (periortbital or mastoid ecchymosis, ota/rhinorrhea), flex neck for meningismus if c-spine injury has been ruled out
- cranial nerve exam: visual fields ± fundoscopy, pupil size and reactivity, extraocular movements, facial strength, hearing to finger rub
- motor: power in deltoids, triceps, wrist extensors, hand interossei, iliopsoas, hamstrings, ankle dorsiflexors, pronator drift
- coordination: finger tapping, finger-to-nose, heel-knee-shin
- gait: tandem gait, heel walking
- reflexes: plantar, biceps, triceps, patellar, ankle
- sensation: all 4 limbs, including double simultaneous stimulation, vibration sense at great toes

CN Innervation of EOM
LR: CN VI, SD: CN IV, Other: CN III

Contraction of the left sternocleidomastoid turns the head right

### Table 3. Approach to Strength Testing of Radiculopathies vs. Peripheral Neuropathies

#### How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerves. Particularly useful peripheral nerve “pairs” are bolded for emphasis.

### Upper Motor Neuron Tests

- **Babinski Reflex**: ‘Up-going’ big toe ± fanning of toes indicates an UMN lesion
- **Hoffman’s Reflex**: Flexion of IP joint of the thumb when tapping/flicking/flexing the nail of the index or ring finger may indicate an UMN lesion if asymmetrical
- **Pronator Drift**: Unable to maintain full arm extension and supination; side of forearm pronation reflects contralateral pyramidal tract lesion; closing eyes accentuates effect

### Pyramidal Pattern of Muscle Weakness (i.e. UMN)

- Weaker arm extendors: shoulder abduction, elbow extension, wrist extension, finger extension, finger abduction
- Weaker leg flexors: hip flexion, knee flexion, ankle dorsiflexion

### MRC Muscle Strength Scale

- 5 Full power
- 4 Submaximal power against resistance (ranging 4+, 4, 4-)
- 3 Full ROM against gravity without resistance
- 2 Full ROM with gravity removed
- 1 Muscle flicker
- 0 No muscle contraction

### Primitive Reflexes

- Grasp, palmomental, root, glabellar tap, snout

### Deep Tendon Reflexes

<table>
<thead>
<tr>
<th>root/muscle</th>
<th>deep tendon reflexes</th>
</tr>
</thead>
<tbody>
<tr>

<td>Hip adductors</td>
</tr>
<tr>
<td>L3/4</td>
<td>Knee extensors</td>
</tr>
<tr>
<td>S1/2</td>
<td>Plantar flexion</td>
</tr>
</tbody>
</table>

### Deep Tendon Reflex Scoring

- 0 Absent
- 1+ Depressed
- 2+ Normal
- 3+ Increased
- 4+ Clonus (≥4 beats)

### Interpreting a Slow or Uncoordinated Rapid Alternating Movement (RAM)

- Slow RMAs without fatiguing is suggestive of weakness (especially if it is asymmetric)
- Slow RMAs with fatiguing (i.e. decreasing amplitude over time) is suggestive of Parkinsonism
- Uncoordinated RAM is suggestive of cerebellar disorder (i.e. ataxia and irregularly irregular rhythm) or ideomotor apraxia
Sensory Exam

- primary sensation
  - spinothalamic tract: crude touch, pain, temperature
  - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
- cortical sensation
  - graphesthesia, stereognosis, extinction, 2-point discrimination

Coordination Exam and Gait

- coordination exam
  - finger-to-nose, heel-to-shin, rapid alternating movements
- stance and gait
  - gait: antalgic, hemiplegic, ataxic, apraxic, festinating, foot drop, broad-based
  - tandem gait (heel-to-toe walking)
  - Romberg test
  - pull test for postural instability

Basic Anatomy Review

![Medulla](image1.png)
![Pons](image2.png)
![Midbrain](image3.png)

**Common Cerebellar Findings**
Frontal executive dysfunction/disinhibition, scanning speech, nystagmus, hypo- or hypermetric saccades, hypotonia, pendular reflexes, terminal tremor, ataxic finger-nose/heel-shin/tandem, wide based stance, positive rebound

**Romberg Test**
Stable with eyes open and closed = normal
Stable with eyes open, falls with eyes closed = positive Romberg, suggesting loss of joint position sense

Myotomes
C5 – Shoulder abduction/elbow flexion
C6 – Wrist extensors
C7 – Elbow extension
C8 – Squeeze hand
T1 – Finger abduction
T2-9 – Intercostal (abdominal reflexes)
T9-10 – Upper abdominals
T11-12 – Lower abdominals
L2 – Hip flexion
L3 – Hip adduction
L4 – Knee extension and ankle dorsiflexion
L5 – Ankle dorsiflexion and big toe extension
S1 – Plantarflexion
Lumbar Puncture

Indications
• diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
• therapeutic: to administer anesthesia, chemotherapy, contrast media; to decrease ICP (pseudotumor cerebri, NPH)

Contraindications
• mass lesion causing increased ICP, could lead to cerebral herniation; CT first if suspect mass lesion
• infection over LP site/suspected epidural abscess
• low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
• uncooperative patient

Complications
• tonsillar herniation (rare)
• SDH
• transient 6th nerve palsy
• post-LP headache (5-40%): worse when upright, better supine; generally onset within 24 h
• prevention: smaller gauge (i.e. 22) needle; reinsert stylet prior to needle removal, blunt-ended needle
• symptomatic treatment: caffeine and sodium benzoate injection
• corrective treatment: blood patch (autologous)
• spinal epidural hematoma
• infection

LP Tubes
• tube #1: cell count and differential: RBCs, WBCs, and differential
  • xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF, diagnostic of SAH)
• tube #2: chemistry: glucose (compare to serum glucose) and protein
• tube #3: microbiology: Gram stain and C&S
  • specific tests depending on clinical situation/suspicion
  • viral: PCR for herpes simplex virus (HSV) and other viruses
  • bacterial: polysaccharide antigens of H. influenzae, N. meningitidis, S. pneumoniae
  • fungal: cryptococcal antigen, culture
  • TB: acid-fast stain, TB culture, TB PCR
• tube #4: cytology: for evidence of malignant cells
• tube #5: cell count: compare RBC count to that of tube #1
  • note: tube 4 or 5 can be sent for repeat cell count

Approach to Common Presentations

Weakness

Approach
• mode of onset: abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrine, neoplastic)
• course: worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
• pattern: objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
• associated symptoms: sensory symptoms, cortical symptoms, spinal symptoms (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
• history: family history, developmental history, medications, risk factors, recent/preceding exposures
• investigations for LMN: NCS/EMG
• investigations for UMN: imaging (brain and/or spinal cord)
Differential Diagnosis
- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  - generalized
  - myopathy (proximal > distal weakness)
    - endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
    - rheumatologic: polymyositis, vasculitis
    - infectious: HIV, CMV, influenza
    - other: collagen vascular disorders, steroids, statins, alcohol, electrolyte disorders
  - NMJ (MG, botulism, LEMS, organophosphate poisoning)
  - cachexia
  - localized
    - UMN (leukodystrophy, vasculitis, abscess, brain tumour, vitamin B₁₂ deficiency, MS, stroke)
    - radicular pain (i.e. nerve root)
    - anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic, lead toxicity)
    - peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
- no objective muscle weakness
  - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  - depression, deconditioning
- if loss of passive motion, consider intra-articular, peri-articular, or extra-articular causes

Numbness/Altered Sensation

Approach
- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, diminution, or absence of feeling
- determine distribution of sensory loss:
  - nerve root vs. peripheral nerve?
  - symmetric stocking-glove pattern? (indicative of distal symmetric polyneuropathy)
  - anterior-posterior spinal cord dissociation
- investigations: NCS, vitamin B₁₂ levels, imaging based on associated findings

Differential Diagnosis
- cerebral: stroke, demyelination, tumour
  - associated symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumour
  - associated symptoms: diplopia, vertigo, dysarthria, dysphagia
- spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B₁₂ deficiency, disc lesion
  - associated symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
- neuropathy: local compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B₁₂ deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

Cranial Nerve Deficits

CN I: Olfactory Nerve

Clinical Features
- absence of sense of smell associated with a loss of taste

Differential Diagnosis
- nasal: physical obstruction
  - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- olfactory neuroepithelial: destruction of receptors or their axon filaments
  - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
- central: lesion of olfactory pathway
  - Kallmann syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeval inflammation, meningioma, aneurysm, PD, stroke, MS
- endocrine/metabolic
  - DM, adrenal hypo/hyperfunction, pseudohypoparathyroidism, hypothyroidism, renal/liver failure, vitamin deficiency
CN II: Optic Nerve

Clinical Features
- palsy (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

Differential Diagnosis
- PComm aneurysm: early mydriasis, then CN III palsy
- cavernous sinus (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus
- ischemia of CN III (DM, temporal arteritis, HTN, atherosclerosis): pupil sparing CN III palsy
- midbrain lesion: complete unilateral CN III palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs ± mydriasis
- orbital lesion: associated with optic neuropathy, chemosis, proptosis
- other (inflammatory, infection, neoplasia, uncal herniation, trauma)

CN IV: Trochlear Nerve

Clinical Features
- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

Differential Diagnosis
- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

CN V: Trigeminal Nerve

Clinical Features
- ipsilateral facial numbness, weakness of muscles of mastication (V3 only) with ptymylogeal deviation towards the side of the lesion

Differential Diagnosis
- brainstem (ischemia, tumour, syringobulbia, demyelination)
- peripheral (tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve)
- trigeminal ganglion (acoustic neuroma, meningioma, fracture of middle fossa)
- cavernous sinus (carotid aneurysm, meningioma, sinus thrombosis)
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

CN VI: Abducens Nerve

Clinical Features
- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

CN IV is the only cranial nerve that crosses the midline and exits posteriorly
A CN IV lesion may cause a contralateral deficit
CN IV is at risk of trauma during neurosurgical procedures involving the midbrain because of its long intracranial course
Jaw deviation is towards the side of a LMN CN V lesion
CN VI has the longest intracranial course and is vulnerable to increased ICP, creating a false localizing sign
Differential Diagnosis
- pons (infarction, hemorrhage, demyelination, tumour): associated with facial weakness and contralateral pyramidal signs
- tentorial orifice (compression, meningioma, trauma): false localizing sign of increased ICP
- cavernous sinus (carotid aneurysm, meningioma, sinus thrombosis)
- ischemia of CN VI (DM, temporal arteritis, HTN, atherosclerosis)
- congenital (Duane’s syndrome)

CN VII: Facial Nerve

Clinical Features
- LMN lesion: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- UMN lesion: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

Differential Diagnosis
- idiopathic = Bell’s palsy, 80-90% of cases (see Otolaryngology, OT23)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay Hunt (HSV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

CN VIII: Vestibulocochlear Nerve

- see Otolaryngology, OT9

CN IX: Glossopharyngeal Nerve

Clinical Features
- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue
- absent gag reflex and dysphagia

Disorders
- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

Differential Diagnosis of Lower Cranial Nerve Deficits (CN IX, X, XI, XII)
Intracranial/Skull Base: meningioma, neurolipoma, metastases, osteomyelitis, meningitis
Intracranial/Skull Base: meningioma, neurolipoma, metastases, osteomyelitis, meningitis
Neck: trauma, surgery, tumours

Normal swallowing is initiated when the tongue moves a bolus back into the palatal archway. Tongue movements are innervated exclusively by CN XII. The bolus stimulates the soft palate to elevate and the bolus is deflected into the oropharynx. Next the pharyngeal constrictors contract, the larynx elevates, and the vocal cords close. Swallowing depends on afferent information via CN V, IX, and X and motor action via CN V, VII, IX, X, and XII. Connections in the nucleus of the tractus solitarius in the medulla (in proximity to the respiratory centre) act as the swallowing centre. Swallowing and breathing are coordinated to prevent aspiration.
CN X: Vagus Nerve

Clinical Features
• oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
  ▪ neuromuscular causes of dysphagia
    • CNS: stroke, cerebral palsy, tumour, trauma, PD, AD, MS
    • CN: DM, laryngeal nerve palsy, polio, ALS
    • myopathic/NMJ: dermatomyositis, polymyositis, MG, sarcoidosis
  ▪ other causes of dysphagia: see Gastroenterology, G8
• dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

CN XI: Accessory Nerve

Clinical Features
• LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
• UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

CN XII: Hypoglossal Nerve

Clinical Features
• LMN lesion: tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
• UMN lesion: tongue deviation away from lesion; absence of atrophy and fasciculations

NAION can be caused by use of sildenafil (Viagra®) in rare cases

If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results. Begin treatment immediately

NAION can be caused by use of sildenafil (Viagra®) in rare cases
**Optic Disc Atrophy**

- **etiologies:** glaucoma, AION, compressive tumour, optic neuritis, Leber’s hereditary optic neuropathy, congenital
- **presentation:** disc pallor, low visual acuity, peripheral vision defect, decreased colour vision
- **treatment:** none (irreversible), aim to prevent

**Abnormalities of Visual Field**

**Visual Fields Defects**

- Right anopsia (right optic nerve lesion)
- Right anopsia and left upper quadrantanopsia (junctional scotoma)
- Bitemporal hemianopsia (chiasmal lesion)
- Left homonymous hemianopsia (right optic tract lesion)
- Left upper quadrantanopsia (right temporal lesion)
- Left lower quadrantanopsia (right parietal lesion)

**Figure 13. Characteristic visual field defects with lesions along the visual pathway**

**Abnormalities of Eye Movements**

**Disorders of Gaze**

**Pathophysiology**

- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

**Clinical Features**

- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can be overcome with doll’s eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
  - cannot be overcome with doll’s eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

**Etiology**

- common: infarcts (frontal or brainstem), MS, tumours

**Internuclear Ophthalmoplegia**

**Pathophysiology**

- results from a lesion in MLF which disrupts coordination between CN VI nucleus in pons and the contralateral CN III nucleus in midbrain → disrupts conjugate horizontal gaze

**Clinical Features**

- horizontal diplopia on lateral gaze, oscillopsia
- on gaze away from the side of the lesion
  - ipsilateral adduction defect
  - contralateral abduction nystagmus
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

**Etiology**

- common: MS, brain stem infarct

**Investigations**

- MRI
Diplopia

Etiology – Monocular (see Ophthalmology, OP7)
- mostly due to relatively benign optical problems (refractive error, cataract) or functional

Etiology – Binocular (due to ocular misalignment)
- muscle
  - Graves’ ophthalmopathy
  - EOM restriction/entrapment
- neuromuscular junction
  - MG (see Myasthenia Gravis, N40)
- cranial nerve palsy (see Cranial Nerve Deficits, N10)
- INO (see Internuclear Ophthalmoplegia, N15)
- other
  - orbital trauma (orbital floor fracture), tumour, infection, inflammation
  - Miller-Fisher variant of GBS
  - Wernicke’s encephalopathy
  - leptomeningeal disease

Approach to Diplopia
- monocular vs. binocular
- horizontal vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

Workup
- may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
- indications for neuroimaging
  - bilateral or multiple nerve involvement
  - severe sudden onset headache (rule out aneurysm)

Nystagmus

- definition: rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- direction of nystagmus is labelled by the rapid component of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

Table 7. Nystagmus Features

*IM = intramuscular; IV = intravenous

- it is also important to consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below

Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications and neurological manifestations
Seizure Disorders and Epilepsy

Seizure

Definitions
- seizure: transient neurological dysfunction caused by excessive activity of cortical neurons, resulting in paroxysmal alteration of behaviour and/or EEG changes
- epilepsy: chronic condition characterized by two or more unprovoked seizures

Classification

Seizure

Unprovoked

Partial

Can secondarily become

Autonomic

Psychiatric

Non-Convulsive

Convulsive

Simple

Complex

Figure 16. Classification of seizures

NOTE: seizures can also be classified using age of onset (childhood/adolescence, adulthood/late [i.e. > age 30]), setting (sleep, upon awakening), EEG (focal, generalized)

Signs and Symptoms
- partial seizures
  - simple or complex can secondarily generalize, or simple → complex → generalized seizures
  - simple (preserved LOC)
    - motor: postural, phonatory, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste, or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
    - psychiatric: symptoms rarely occur without impairment of consciousness and are more commonly complex partial
  - complex (altered LOC)
    - patient may appear to be awake but with impairment of awareness
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysmnesic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness
- generalized seizures (decreased LOC)
  - absence (petit mal): usually only seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - clonic: repetitive rhythmic jerking movements
  - tonic: muscle rigidity in flexion or extension
  - tonic-clonic (grand mal, generalized tonic-clonic [GTC])
    - prodrome of unease or irritability hours to days before the episode
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
    - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours
  - myoclonic: sporadic contractions localized to muscle groups of one or more extremities
  - atonic: loss of muscle tone leading to drop attack

Temporal lobe epilepsy is suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations

Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

</tbody>
</table>

*Pseudoseizures do not rule out seizures (not uncommon to present with both)

- Alcoholic withdrawal seizures may occur up to 2 days from the last exposure to alcohol (see Emergency Medicine, ER54)

**Investigations**
- CBC, electrolytes, fasting blood glucose, Ca²⁺, Mg²⁺, ESR, Cr, liver enzymes, CK, prolactin
- Also consider toxicology screen, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
- LP (if fever or meningismus)
- EEG

**Treatment**
- Avoid precipitating factors
- Indications for medical therapy (anticonvulsants): 2 or more unprovoked seizures, known organic brain disease, EEG with epileptiform activity, first episode of status epilepticus, abnormal neurologic examination or findings on neuroimaging
- Psychosocial issues: stigma of seizures, education of patient and family, status of driver’s license, pregnancy issues
- Safety issues: driving, operating heavy machinery, bathing, swimming alone
- Consider surgical treatment if focal and refractory

**Status Epilepticus**

- **Definition:** unremitting seizure or successive seizures without return to a baseline state of greater than 5 min
- **Complications:** anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
• initial measures: ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal O₂, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
• blood work: electrolytes, Ca²⁺, Mg²⁺, PO₄³⁻, glucose, CBC, toxicology screen, EtOH level, AED levels
• focused history: onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
• physical exam (once seizures controlled): LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
• post-treatment stabilization: CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

Figure 17. Status epilepticus treatment algorithm

Antiepileptic Drugs
• generalized-onset and partial-onset seizures: lamotrigine (Lamictal*), levetiracetam (Keppra*), rufinamide (Banzel*), topiramate (Topamax*), valproic acid (Depakene*, Apo-Valproic*), divalproex sodium (Epival*), zonisamide
• partial seizures (simple partial, complex partial, and secondarily generalized seizures): carbamazepine (Tegretol*), gabapentin (Neurontin*), lacosamide (Vimpat*), oxcarbazepine (Trileptal*), phenobarbital (Phenobarb*), phenytoin (Dilantin*), pregabalin (Lyrica*), primidone, tiagabine (Gabitril*), vigabatrin (Sabril*) note: these drugs may exacerbate generalized seizures
• absence seizures: ethosuximide (Zarontin*)

**Mild Neurocognitive Disorder (Mild Cognitive Impairment)**

**Definition**
- cognitive impairment not meeting criteria of Major Neurocognitive Disorder
- several criteria proposed with considerable overlap
- in general, criteria include a measurable cognitive deficit in at least one domain reported by patient or others without impairment in ADLs and in the absence of Major Neurocognitive Disorder
- amnestic (precursor to AD) vs. Non-amnestic MCI

**Pathophysiology**
- genetic factors
  - minority (<7%) of AD cases are familial (autosomal dominant)
  - 3 major genes for autosomal dominant AD have been identified:
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
    - the E4 polymorphism of apolipoprotein E (ApoE) is a susceptibility genotype (E2 is protective)
    - note: ApoE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (not necessarily specific for AD)
  - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
    - senile plaques (extracellular deposits of amyloid in the grey matter of the brain)
    - loss of synapses
    - neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
    - loss of cholinergic neurons in nucleus basalis of Meynert which normally project diffusely throughout the cortex

**Delirium**
- a medical emergency carrying significant risk of morbidity and mortality; it is characterized by acute onset, disorientation, fluctuating level of consciousness, poor attention, and marked psychomotor changes

**Visual hallucinations**
- more commonly indicate organic disease
biochemical pathology
- 50-90% reduction in action of choline acetyltransferase

Epidemiology
- published prevalence rates vary from 2-4 percent to more than 20 percent due to different diagnostic criteria and measuring instruments

Risk Factors
- elevated blood pressure, obesity, cardiac disease, and apolipoprotein E epsilon 4 genotype associated with increased risk of mild NCD

Signs and Symptoms
- cognitive impairment
  - particularly in amnestic subtype
  - important to ascertain that memory complaints represent change from baseline
  - patients with mild NCD are often troubled by memory symptoms in comparison to patients with dementia
- neuropsychiatric symptoms
  - depression (50%), irritability, anxiety, aggression, and apathy

Investigations
- establish a baseline for follow-up
- office evaluation
  - clinical interview is the cornerstone of mild NCD evaluation
  - ideally informants should be involved in the interview
  - consider drop-off in personal care and ADLs at later stage
- neuropsychological testing
  - MMSE or MoCA
  - should not be used in isolation
  - if abnormal, follow-up in one year to monitor for cognitive and functional decline
- neuroimaging
  - role uncertain
  - most advocate for a non-contrast brain CT to evaluate for structural abnormalities (CVD, SDH, NPH, or mass lesion)
- other testing
  - exclude treatable conditions and underlying psychiatric conditions

Treatment
- watch and wait
- no evidence for cholinesterase inhibitors, anti-inflammatory agents, vascular risk factor modification, exercise, cognitive interventions

Prognosis
- 10% progress to dementia per yr
- typically progress to dementia over a period of 2-3 yr

Major Neurocognitive Disorder (formerly Dementia)
- see Psychiatry, PS21 and Geriatric Medicine, GM4

Definition
- an acquired, generalized, and (usually) progressive impairment of cognitive function (i.e. memory, recall, orientation, language, abstraction) associated with impairment in activities of daily living (i.e. planning, shopping, food preparation, difficulties with finances)
- affects comprehension, but not level of consciousness
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
  A) concern of the individual or a knowledgeable informant AND
  B) a substantial impairment in cognitive performance either documented by standardized neuropsychological testing, or quantified clinical assessment
- see Psychiatry, PS21 for DSM-5 diagnostic criteria
- differentiated from mild NCD (formerly mild cognitive impairment) by the extent to which the impairment affects ADLs
  - mild NCD represents an intermediate stage between dementia and normal aging
  - by definition, IADLs are not affected in mild NCD

Epidemiology
- major NCD (dementia): 1-2% at age 65 yr and reaching as high as 30% by age 85 yr
- mild NCD: 2-10% at age 65 yr and 5-25% by age 85 yr
- **note** major NCD due to Alzheimer's disease is uncommon before age 60 yr
- major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with age

**Etiology**
- see Table 13 for common causes of dementia
- see Table 14 for acquired causes of dementia
- reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, NPH, depression (pseudodementia), intracranial tumour, SDH, hypercalcemia (secondary to elevated PTH)
- must rule out delirium

**History**
- "geriatric giants"
  - confusion/incontinence/falls/polypharmacy
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS
- alcohol, smoking
- OTCs, herbal remedies, medications (sedative hypnotics, antipsychotics, antidepressants, anticholinergics), compliance, accessibility
- history of vascular disease or head trauma
- collateral history

**Investigations**
- depends on suspected etiologies (see Tables 13 and 14)
  - blood pressure
  - hearing and vision
  - neurological exam with attention to signs of parkinsonism, UMN findings, CVD
  - general physical exam depending on risk factors and history
  - MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)
  - blood pressure
  - neurological exam with attention to signs of parkinsonism, UMN findings, CVD
  - OTCs, herbal remedies, medications (sedative hypnotics, antipsychotics, antidepressants, anticholinergics), compliance, accessibility
  - history of vascular disease or head trauma
  - collagen history

**Physical Exam**
- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings, CVD
- general physical exam depending on risk factors and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

- Trauma (head injury)
- Anoxia
- Endocrine (hypothyroid)
- Space occupying lesion (chronic SDH)
- Toxic (alcohol)

**Cholinesterase Inhibitors for Dementia with Lewy Bodies (DLB), Parkinson’s Disease (PDD) and Cognitive Impairment in Parkinson’s Disease (CIND-PD)**
- **Cochrane DB Syst Rev 2012;3:CD006504**
- **Study:** Meta-analysis of RCTs assessing efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD.
- **Results:** The six trials (n = 1,236) included demonstrated therapeutic benefit of cholinesterase inhibitors for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase inhibitors were associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine than donepezil, husted or bold. Withdrawal occurred in the treatment group (OR 0.29).
- **Conclusion:** Current evidence supports use of cholinesterase inhibitors for patients with PDD but its role in DLB and CIND-PD is still unclear.

**Major or Mild NCD due to Alzheimer’s Disease**

- see Psychiatry, PS22

**Definition**
- beyond criterion for NCD, the core features of major or mild NCD due to Alzheimer’s disease include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnestic (i.e. impairment in memory and learning - impaired ability to learn new information)
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate-severe phase: visuocognitive/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnestic presentation (one of the following)
  1. aphasia: language disturbance
  2. apraxia: impaired ability to carry out motor activities despite intact motor function
  3. agnosia: failure to recognize or identify objects despite intact sensory function
- note: there may be no evidence of mixed etiology (i.e. absence of other neurodegenerative or CVD)

**Pathophysiology**
- genetic factors
  - minority (<7%) of AD cases are familial (autosomal dominant)
  - 3 major genes for autosomal dominant AD have been identified:
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
    - the E4 polymorphism of apolipoprotein E (APOE) is a susceptibility genotype (E2 is protective)
  - note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (although not necessarily specific for AD)
  - gross pathology
    - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
    - senile plaques (extracellular deposits of amyloid in the grey matter of the brain)
    - loss of synapses
    - neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
    - loss of cholinergic neurons in nucleus basalis of Meynert that project diffusely throughout the cortex
  - biochemical pathology
    - 50-90% reduction in action of choline acetyltransferase

**4 As and one D of AD**

- Anterograde amnesia
- Aphasia
- Apraxia
- Agnosia
- Disturbance in executive function

(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

Down syndrome predisposes to early onset of Alzheimer’s (i.e. age of ~40) due to three copies of the amyloid gene (APP)
Epidemiology
• 1/12 of population 65-75 yr of age
• up to 1/3 population >85 yr of age
• accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

Risk Factors
• age is the largest risk factor
• genetic susceptibility polymorphism: apolipoprotein E4 increases risk and decreases age of onset
• other factors include: traumatic brain injury, family history, Down syndrome, low education, and presence of multiple vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

Signs and Symptoms
• cognitive impairment
  ▫ memory impairment for newly acquired information (early)
  ▫ deficits in language, abstract reasoning, and executive function
• behavioural and psychiatric manifestations (80% of those with major NCD)
  ▫ mild NCD: major depressive disorder and/or apathy
  ▫ major NCD: psychosis, irritability, agitation, combative, and wandering
• motor manifestations (late)
  ▫ gait disturbance, dysphagia, incontinence, myoclonus, and seizures
  ▫ parkinsonism (if present consider DLB)

Investigations
• perform investigations to rule out other potentially reversible causes of dementia
• EEG: usually normal, may observe generalized slowing (nonspecific)
• MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
• SPECT: hypoperfusion in temporal and parietal lobes
• PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of beta-amyloid plaque in neuronal tissue

Treatment
• acetylcholinesterase inhibitors have been shown to slow decline in cognitive function
  ▫ donepezil, rivastigmine, galantamine
• relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
• galantamine is contraindicated in patients with hepatic/renal impairment
• memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
• symptomatic management
  1. pharmacologic
     ▫ low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
     ▫ trazodone for sleep disturbance
     ▫ antidepressants (SSRIs)
  2. non-pharmacologic
     ▫ redirection
     ▫ explore inciting factors for behaviour and modify behaviour of patient or caregiver
     ▫ family support and day care facilities

Prognosis
• mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
• in those who survive the full course, death commonly results from aspiration

Major or Mild NCD with Lewy Bodies
(formerly Dementia with Lewy Bodies)

Definition
• A NCD that includes not only progressive cognitive impairment (with early changes in complex attention and executive function rather than learning and memory), but also recurrent complex visual hallucinations
• core diagnostic features
  ▫ fluctuating cognition with pronounced variations in attention and alertness
  ▫ recurrent visual hallucinations that are well formed and detailed
  ▫ spontaneous features of parkinsonism, with onset subsequent to development of cognitive decline (rest tremor may be absent in DLB, but otherwise same classic features of Parkinson’s disease)
• suggestive/supportive features
  ▫ meets criteria for rapid eye movement (REM) sleep behaviour disorder
  ▫ severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)

Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer’s Disease: Outcomes from CATIE-AD
Am J Psychiatry 2011;168:831-839
Study: 421 outpatients with Alzheimer’s disease and psychosis or agitated/aggressive behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blinded RCT. MMSE and Alzheimer’s Disease Assessment Scale (ADAS) scores were measured at 36 wk.
Results: Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (- 0.067/wk vs. -0.007/wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.001/wk).
Conclusions: Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.
repeated falls, syncope, or transient episodes of unexplained loss of consciousness
- auditory or other nonvisual hallucinations, systematic delusions, and depression may also be present

**Etiology and Pathogenesis**
- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

**Diagnostically Suggestive Markers**
- low striatal dopamine transporter uptake on SPECT or PET
- relative preservation of medial temporal structures on CT/MRI

**Epidemiology**
- 0.1-5% of the general elderly population
- Lewy bodies are present in 20-35% of all dementia cases (more common in males)

**Treatment**
- acetylcholinesterase inhibitors (e.g. donepezil)

**Prognosis**
- average duration of survival 5-7 yr

---

**Major or Mild Frontotemporal NCD**
*(formerly Frontotemporal Dementia)*

**Definition**
- refers to a group of disorders caused by progressive cell degeneration in the brain's frontal or temporal lobes
- there are several variants of FTD each with specific core symptoms
- nevertheless, there is overlap between variants (i.e. NCD criteria along with relative sparing of learning and memory and perceptual-motor function)
- common neurocognitive symptoms include deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, and increased distractibility)
- “probable” is distinguished from “possible” frontotemporal NCD by:
  - evidence of causative frontotemporal NCD genetic mutation, from either family history or genetic testing
  - evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
  - evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or SPECT

**Behavioural Variant FTD**
- most common variant; disinhibition and apathy are common symptoms
- insidious onset: must show progressive deterioration of behaviour and/or cognition by observation or history
- prominent decline in social cognition and/or executive abilities
- typically early symptom presentation (i.e. within the first 3 yr)
- three out of the following symptoms must be present and persistent/recurrent:
  - behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
  - apathy or inertia
  - loss of sympathy or empathy (diminished response to others’ needs/feelings, social interest)
  - preservative, stereotyped, or compulsive/ritualistic behaviour
  - hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)

**Language Variants (Primary Progressive Aphasia)**
- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization (“thing”) or supraordinate categories (“animal” for “dog”)
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition
FTD Movement Disorders
- corticobasal degeneration (CBD): shakiness, lack of coordination, muscle rigidity and spasms
- progressive supranuclear palsy (PSP): walking and balance problems; frequent falls and muscle stiffness

Etiology and Pathogenesis
- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (Tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes; cortical thinning; possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

Epidemiology
- fourth most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals younger than 65 yr

Prognosis
- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical Alzheimer's disease

Major or Mild Vascular NCD

Definition
- diagnosis of major or mild NCD with determination of CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
  - evidence of the presence of CVD from history, physical exam, and/or neuroimaging that is sufficient to account for the neurocognitive deficits
  - neuroimaging evidence of cerebrovascular disease comprises one or more of the following:
    - one or more large vessel infarct or hemorrhage
    - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
    - two or more lacunar infarcts outside the brainstem
    - extensive and confluent white matter lesions
    - for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
    - for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease and one or more lacunae is generally necessary
    - associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

Etiology and Pathogenesis
- major risk factors are the same as those for CVD (i.e. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

Epidemiology
- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages 80+) to 44.6% (ages 90+)
- higher prevalence in African Americans compared to Caucasians and East Asians
- prevalence higher in males than in females

Creutzfeldt-Jakob Disease
- rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
- investigations: CSF analysis, MRI brain (cortical and/or subcortical FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy
- no treatments currently exist
Normal Pressure Hydrocephalus

- see Neurosurgery, NS8

Aphasia

Definition
- an acquired disturbance of language characterized by errors in speech production, writing, comprehension, or reading

Neuroanatomy of Aphasia
- Broca’s area (posterior inferior frontal lobe) involved in speech production (expressive)
- Wernicke’s area (posterior superior temporal lobe) involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke’s area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke’s and Broca’s areas

Assessment of Language
- assessment of context
  - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  - spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)

Apaxia classification

Figure 19. Aphasia classification

Apraxia

Definition
- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention
Clinicalpathological Correlations

Table 15. Apraxia

<table>
<thead>
<tr>
<th>Description</th>
<th>Tests</th>

Mild Traumatic Brain Injury

Definition

• mild TBI = concussion
• trauma induced transient alteration in mental status that may involve loss of consciousness
• hallmarks of concussion: confusion and amnesia, which may occur within minutes
• loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h

Epidemiology

• 75% of TBIs are estimated to be mild; remainder are moderate or severe (see Neurosurgery, NS31 and Emergency Medicine, ER9)
• highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features

• impairments following mild TBI
  • somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
  • cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  • emotion and behaviour: impulsivity, irritability, depression
  • severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
  • associated conditions: brain contusion, diffuse axonal injury, C-spine injury

Investigations

• neurological exam to identify focal neurologic deficits
• neurocognitive assessment
  • simple orientation questions are inadequate to detect cognitive changes
  • initial assessment of severity is determined by
    • Glasgow Coma Scale: mild: 13-15, moderate: 9-12, severe: 3-8
    • sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
• neuroimaging
  ▪ x-ray of skull: not indicated for routine evaluation of MTBI
  ▪ CT head as indicated by Canadian CT Head Rules (see Emergency Medicine, ER8)
  ▪ MRI not indicated in initial evaluation – indicated in presence of continued or worsening symptoms despite normal CT

Treatment
• observation for first 24 h after mild TBI in all patients because of risk of intracranial complications
• emergency department for assessment if any loss of consciousness or persistent symptoms
• hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
• early rehabilitation to maximize outcomes
  ▪ OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
• pharmacological management of headaches, pain, depression
  ▪ CBT, relaxation therapy
• follow Return to Play guidelines (www.thinkfirst.ca)

Prognosis
• most recover from mild TBI with minimal treatment, but some experience long-term consequences
• athletes with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
• repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
• sequelae include
  ▪ post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  ▪ post-traumatic headaches: begin within 7 d of injury
  ▪ post-traumatic epilepsy: two-fold increase in risk of epilepsy in 5 yr post-TBI, prophylactic anticonvulsants not effective
  ▪ post-traumatic vertigo

</tr>
<tr>
<td>Tics</td>
</tr>
<tr>
<td>Tremor</td>
</tr>
</tbody>
</table>

In some cases, dystonias may only occur during voluntary movement and sometimes only during specific activities such as writing, chewing, or speaking.

Hemiballismus is most often due to a vascular lesion of the contralateral subthalamic nucleus.

Some myoclonus is stimulus sensitive and can be induced by noise, movement, light, visual threat, or pinprick.
Function of the Basal Ganglia

- The cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, which then activate two pathways: direct and indirect.
  - Direct: cortex → striatum → GPi/SNr → thalamus → motor cortex
    * Activation of this pathway removes the inhibitory effect of the GPi on the thalamus, letting the thalamus activate the cortex and ultimately allowing movement.
  - Indirect: cortex → striatum → GPe → STN → GPi/SNr → thalamus → motor cortex
    * Activation of this pathway causes inhibition of the thalamus and ultimately prevents movement.

**Figure 21. Horizontal section of basal ganglia**
**Movement Disorders**

Differential Diagnoses
1. Tremor
   - **postural:** physiologic, anxiety, sedative/alcohol withdrawal, drug toxicity, heavy metal poisoning, carbon monoxide poisoning, thyrotoxicosis, benign essential tremor, cerebellar, Wilson's disease
     - benign essential tremor is a common autosomal dominant trait that presents as a bilateral postural tremor of the vertical axis, especially in the upper extremities
   - **intention:** brainstem lesion, cerebellar lesion, alcohol, anticonvulsants, sedatives, Wilson's disease
   - **resting:** Parkinsonism, Wilson's disease, mercury poisoning

</tr>
</tbody>
</table>

2. Chorea: Huntington’s disease, neuroacanthocytosis, SLE, APLA syndrome, Wilson’s disease, CVD, tardive dyskinesia, senile chorea, Sydenham’s chorea, pregnancy chorea

3. Dystonia
   - **primary dystonia:** familial, sporadic (torticollis, blepharospasm, writer’s cramp)
   - **dystonia-plus syndromes:** dopa-responsive dystonia, myoclonus-dystonia
   - **secondary dystonia:** thalatomy, stroke, CNS tumour, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
   - **heredodegenerative dystonias:** Parkinsonian disorders, Wilson’s disease, Huntington’s disease

4. Myoclonus
   - **physiologic myoclonus:** hiccups, nocturnal myoclonus
   - **essential myoclonus
   - **epileptic myoclonus
   - **symptomatic myoclonus**
     - degenerative disorders (Wilson’s disease, Huntington’s disease, Corticobasal degeneration)
     - infectious disorders (CJD, viral encephalitis, AIDS-dementia complex)
     - metabolic disorders (drug intoxication/withdrawal, hypoglycemia, hyponatremia, HONK, hepatic encephalopathy, uremia, hypoxia)
     - focal brain damage (head injury, stroke, mass)

5. Tics
   - **primary tic disorders:** transient tic disorder, chronic tic disorder, Gilles de la Tourette, adult onset or senile
   - **secondary tic disorders:** encephalitis, CJD, Sydenham’s chorea, head trauma, drugs, mental retardation syndromes
   - association with OCD and ADHD

### Parkinson’s Disease

**Etiology**
- **sporadic:** combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- **familial** (10%): autosomal dominant α-synuclein mutations, autosomal recessive parkin gene or DJ-1 gene mutation (juvenile onset)
- **MPTP** (neurotoxin)

**Epidemiology**
- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neuro-degenerative disorder, after Alzheimer’s
- mean age of onset is 60 yr

In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson’s disease), and CT/MRI (cerebellar disease) as indicated by type of tremor

> 90% of essential tremor does not need treatment

Most common cause of chorea is drug therapy for PD

Palatal myoclonus can result from lesion to the Dentato-Rubro-Olivary tract, and is associated with an audible clicking

Key Parkinsonian Features
- **TRAP**
  - Tremor (resting)
  - Rigidity
  - Akinesia/bradykinesia
  - Postural instability

**Diagnostic Criteria**
- Bradykinesia, plus one of: resting tremor, muscle rigidity, postural instability not caused by other factors, OR
- 3 or more of the following features:
  - Resting tremor
  - Unilateral onset
  - Persistent asymmetry, with side of onset most affected
  - Progressive disorder
  - Excellent response (70-100%) to levodopa
  - Severe levodopa-induced chorea
  - Response to levodopa for 5 yr or more
  - Clinical course lasting 10 yr or more
Risk Factors
- family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

Pathophysiology
- loss of dopaminergic neurons in pars compacta of substantia nigra, thus reduced dopamine in striatum leading to disinhibition of the indirect pathway and decreased activation of the direct pathway causing increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

Signs and Symptoms
- positive motor
  - resting tremor: asymmetric 4-5 Hz “pill-rolling” tremor, especially in hands
  - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- negative motor
  - bradykinesia: slow, small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls, festinating gait
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, later findings of orthostatic hypotension

Treatment
- pharmacologic
  - mainstay of treatment: levodopa/carbidopa (Sinemet®). Levodopa is a dopamine precursor; carbidopa decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
  - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration (“wearing-off”), random oscillations of on-off symptoms
  - major complication of levodopa is dyskinesia
- treatment of early PD: dopamine agonists, amantadine, MAOI
- adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- surgical: thalamotomy, pallidotomy, deep brain stimulation (thalamic, pallidal, subthalamic)
- psychiatric

Other Parkinsonian Disorders
- dementia/NCD with Lewy bodies (see Behavioural Neurology, N21)
- progressive supranuclear palsy: tauopathy with limited vertical gaze (classically downgaze), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- corticobasal degeneration: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon; may also present as progressive non-fluent aphasia
- multiple system atrophy: synucleinopathy presenting as either cerebellar predominant (previously olivopontocerebellar atrophy or OPCA) or parkinsonism predominant (previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- vascular parkinsonism: multi-infarct presentation with lower body parkinsonism

Huntington’s Disease
Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington’s gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

Risk Factors
- family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

Pathophysiology
- loss of dopaminergic neurons in pars compacta of substantia nigra, thus reduced dopamine in striatum leading to disinhibition of the indirect pathway and decreased activation of the direct pathway causing increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

Signs and Symptoms
- positive motor
  - resting tremor: asymmetric 4-5 Hz “pill-rolling” tremor, especially in hands
  - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- negative motor
  - bradykinesia: slow, small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls, festinating gait
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, later findings of orthostatic hypotension

Treatment
- pharmacologic
  - mainstay of treatment: levodopa/carbidopa (Sinemet®). Levodopa is a dopamine precursor; carbidopa decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
  - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration (“wearing-off”), random oscillations of on-off symptoms
  - major complication of levodopa is dyskinesia
- treatment of early PD: dopamine agonists, amantadine, MAOI
- adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- surgical: thalamotomy, pallidotomy, deep brain stimulation (thalamic, pallidal, subthalamic)
- psychiatric

Other Parkinsonian Disorders
- dementia/NCD with Lewy bodies (see Behavioural Neurology, N21)
- progressive supranuclear palsy: tauopathy with limited vertical gaze (classically downgaze), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- corticobasal degeneration: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon; may also present as progressive non-fluent aphasia
- multiple system atrophy: synucleinopathy presenting as either cerebellar predominant (previously olivopontocerebellar atrophy or OPCA) or parkinsonism predominant (previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- vascular parkinsonism: multi-infarct presentation with lower body parkinsonism

Huntington’s Disease
Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington’s gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

Risk Factors
- family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

Pathophysiology
- loss of dopaminergic neurons in pars compacta of substantia nigra, thus reduced dopamine in striatum leading to disinhibition of the indirect pathway and decreased activation of the direct pathway causing increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

Signs and Symptoms
- positive motor

- surgical: thalamotomy, pallidotomy, deep brain stimulation (thalamic, pallidal, subthalamic)
- psychiatric

Other Parkinsonian Disorders
- dementia/NCD with Lewy bodies (see Behavioural Neurology, N21)
- progressive supranuclear palsy: tauopathy with limited vertical gaze (classically downgaze), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- corticobasal degeneration: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon; may also present as progressive non-fluent aphasia
- multiple system atrophy: synucleinopathy presenting as either cerebellar predominant (previously olivopontocerebellar atrophy or OPCA) or parkinsonism predominant (previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- vascular parkinsonism: multi-infarct presentation with lower body parkinsonism

Huntington’s Disease
Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington’s gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway
Epidemiology
- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr; but varies with degree of anticipation from 5-70 yr

Signs and Symptoms
- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to frank dementia, psychosis, and chorea
  - dementia: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parkakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence

Investigations
- MRI: enlarged ventricles, atrophy of cerebral cortex and caudate nucleus
- genetic testing
  - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
  - CAG repeats on chromosome 4p16.3 that encodes the protein huntingtin

Treatment
- no disease altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

Dystonia

Epidemiology
- third most common movement disorder after Parkinson's disease and essential tremor

Clinical Features
- symptoms exacerbated by fatigue, stress, emotions; relieved by sleep or specific tactile/proprioceptive stimuli ('geste antagoniste', e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalize if younger onset or leg dystonia

Treatment
- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), benzodiazepines, dopamine antagonists (reserpine, neuroleptics); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotactic thalamotomy (unilateral dystonia), posterovenal pallidotomy

Tic Disorders

Definition
- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - onset before age 18 yr
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

Clinical Classification
- **Tourette's disorder**: multiple motor and one or more vocal tics that have persisted for more than 1 yr since onset
- **persistent (chronic) motor or vocal tic disorder**: single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for more than 1 yr since onset
- **provisional tic disorder**: single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- **other specified or unspecified tic disorder**: symptoms characteristic of a tic disorder but do not meet full criteria

Motor vs. Vocal Tics
- simple tics tend to be of short duration (milliseconds)
- complex tics tend to be longer (seconds) and often include a combination of simple tics
- complex tics may often appear to be purposeful

Botulinum toxin (BOTOX®) acts by preventing ACh release at the neuromuscular junction.
• motor tics
  † simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  † dystonic: bruxism (grinding teeth), abdominal tension, sustained mouth opening
  † complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
• vocal tics
  † simple: blowing, coughing, grunting, throat clearing
  † complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

Treatment
• dopamine blocker

Tourette’s Syndrome
(Gilles de la Tourette’s Syndrome)

Definition According to DSM 5
1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted for more than 1 yr since first tic onset (with no tic-free periods greater than 3 mo)
3. onset is before age 18 yr
4. not due to effect of a substance or another medical condition

Epidemiology
• estimated prevalence among adolescents 3-8 per 1,000 school-age children; M:F = 2:1 to 4:1

Signs and Symptoms
• tics: wide variety that wax and wane in type and severity; can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
  † can be worsened by anxiety, excitement, and exhaustion; better during calm focused activities
• psychiatric: compulsive behaviour (associated with OCD and ADHD), hyperactive behaviour, ‘rages’, sleep-wake disturbances, learning disabilities

Treatment
• clonidine, clonazepam

Prognosis
• typically begins between ages 4-6
• peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by 18 yr of age)
• tic symptoms, however, can manifest similarly in all age groups and across the lifespan

Cerebellar Disorders

Clinico-Anatomic Correlations
• vermis: trunk/gait ataxia
• cerebellar lobe (i.e. lateral): rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

Symptoms and Signs of Cerebellar Dysfunction
• nystagmus: observe during extraocular movement testing (most common is gaze-evoked nystagmus)
• dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/slurred speech on spontaneous speech (see CN X Vagus Nerve, N13)
• ataxia: broad-based, uncoordinated, lurching gait
• dysmetria: irregular placement of voluntary limb or ocular movement
• dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation – supination task)
• postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
• intention tremor: typically orthogonal to intended movement, and increases as target is approached
• hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
• pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres)
• rebound phenomenon: overcorrection after displacement of a limb
• hypometric and hypermetric saccades
  † pendular reflexes at triceps

Wernicke-Korsakoff Syndrome

- see Psychiatry, PS25
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

Cerebellar Ataxias

Congenital Ataxias
- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

Hereditary Ataxias
- autosomal recessive: includes Friedrich's ataxia, ataxia telangiectasia, vitamin E deficiency
  - Friedrich's ataxia: prevalence 2/100,000; onset between 8 and 15 yr
    - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
    - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (30 types, most due to CAG repeats)
  - signs: ataxia and dysarthria; ± myoclonus, chorea, polyneuropathy, pyramidal or extrapyramidal features, hyporeflexia, seizures, dementia

Acquired Ataxias
- neurodegeneration (e.g. multiple system atrophy)
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson's, thiamine deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

Vertigo

- see Otolaryngology, OT12

Gait Disturbances

Approach to Gait Disturbances

1. Characterization of the gait disturbance
   - posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, elaborate/inconsistent movements, standing from sitting
2. Identification of accompanying neurologic signs
   - full neurological exam required (diagnosis often can be made by P/E alone)
3. Identify red flags
   - sudden onset, cerebellar ataxia, paresis (hemipara, para- or quadri-), bowel/bladder incontinence
4. Workup
   - based on etiology – requires blood work, neuroimaging, and urgent neurologist referral

Motor Neuron Disease

Amyotrophic Lateral Sclerosis (Lou Gehrig’s Disease)

Definition
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

Etiology
- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

Pathology
- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

Epidemiology
- 5/100,000; incidence increases with age

Signs and Symptoms
- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles, and sphincters

Investigations
- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

Treatment
- riluzole (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine (Zanaflex®), regular exercise, and physical therapy
  - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular Botox® (rare)
  - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. PEG tube), rehabilitation (PT, OT, SLP), psychosocial support

Prognosis
- median survival 3 yr; death due to respiratory failure

Other Motor Neuron Diseases

- degenerative
  - progressive muscular atrophy (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres
  - primary lateral sclerosis (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal with variable disability; 5-10% of patients in ALS centres
  - spinal muscular atrophy: pediatric disease with symmetric LMN symptoms
- infectious
  - post-polio syndrome: residual asymmetric muscle weakness, atrophy
- acquired
  - multifocal motor neuropathy: conduction block on NCS, asymmetric LMN symptoms, ± anti-GM1, treatable with IVIG
Peripheral Neuropathies

Diagnostic Approach to Peripheral Neuropathies

1. differentiate: motor vs. sensory vs. autonomic vs. mixed
2. pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. history: PMH, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

Classification

- monoradiculopathy: dermatomal deficit due to single nerve root lesion
  - due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- polyradiculopathy: multiple dermatome deficits due to multiple nerve root lesions
  - one type is cauda equina syndrome (lumbosacral roots)
- plexopathy: deficit matching distribution of a nerve plexus
  - brachial plexopathy
    - upper (C5-C7): LMN sx of shoulder and upper arm muscles (Erb's palsy)
    - lower (C8-T1): LMN sx and sensory sx of forearm and hand (Klumpke's palsy)
  - DDx: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome
    - (i.e. cervical rib)
- lumbosacral plexopathy (rare, especially unilateral)
  - DDx: idiopathic neuritis, infarction (i.e. DM), compression

- mononeuropathy: single nerve deficit
  - carpal tunnel syndrome (most common); compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel’s sign, Phalen’s test, thenar muscle wasting, sensory deficit
    - EMG and NCS: slowing at wrist (both motor and sensory)
  - etiology: entrapment, pregnancy, DM, gammapathy, rheumatoid arthritis, thyroid disease
  - Bell’s palsy (most common cranial neuropathy): see Otolaryngology, OT23
    - other less common mononeuropathies due to entrapment/compression: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)

- mononeuropathy multiplex: deficit affecting multiple discrete nerves (asymmetric)
  - must rule out vasculitis or collagen vascular disease

- polyneuropathy: symmetrical distal stocking-glove pattern
  - symmetrical distal sensorimotor deficit affecting longest fibres first (stocking-glove distribution), hypotonia; progression of dysesthesia early and weakness later
  - etiology: DM (most common), renal disease, substances, toxins, genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia

- chronic inflammatory demyelinating polyneuropathy (CIDP)
  - chronic relapsing sensorimotor polyneuropathy with increase protein in CSF and demyelination (shown on EMG/NCS)
    - course is fluctuating, in contrast with the acute onset of GBS
  - treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

A = autonomic; CIDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; OGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPEP = serum protein electrophoresis

Guillain-Barré Syndrome
- **definition:** acute rapidly evolving demyelinating inflammatory polyneuropathy that often starts in the distal lower limbs and ascends
- **etiology**
  - autoimmune attack and damage to peripheral nerve myelin
  - sometimes preceded by viral/bacterial infections
- **signs and symptoms**
  - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
  - motor: weakness starting distally in legs, areflexia
  - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- **investigations**
  - CSF: albuminocytologic dissociation (high protein, normal WBC)
  - EMG/NCS: conduction block, differential or focal (motor > sensory) slowing, decreased F-wave, sural sparing
- **subtypes**
  1. acute inflammatory demyelinating polyneuropathy (AIDP)
  2. acute motor-sensory axonal neuropathy (AMSAN)
  3. acute motor axonal neuropathy (AMAN)
- **treatment**
  - IVIG or plasmapheresis, ± pain management, monitor vitals and vital capacity
- **prognosis**
  - peak of symptoms at 2-3 wk, resolution at 4-6 wk
  - 5% mortality (higher if require ICU); up to 15% have permanent deficits

Neuromuscular Junction Diseases

Clinical Approach to Disorders of the Neuromuscular Junction

<td>Decremental response</td>
<td>Incremental response</td>
<td>↑ (rapid stimulation) ↓ (slow stimulation)</td>
</tr>
</tbody>
</table>
**Myasthenia Gravis**

**Etiology and Pathophysiology**
- progressive autoimmune disorder due to anti-AChR antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

**Epidemiology**
- bimodal age of onset – 20s (mostly women) and 60s (mostly men)

**Signs and Symptoms**
- see Table 21
- fatigable, symmetric or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

**Investigations**
- edrophonium (Tensilon®) test
  - assess for improvement over 2 min following edrophonium injection
- EMG
  - repetitive stimulation → decremental response
  - single fibre electromyography shows increased jitter (80-100% sensitivity)
  - spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
- anti-acetylcholine receptor antibody assay (70-80% sensitivity)
- CT/MRI to screen for thymoma/thymic hyperplasia

**Treatment**
- thymectomy
  - 85% of patients show improvement or remission
- symptomatic relief
  - acetylcholinesterase inhibitors (e.g. pyridostigmine)
  - does not affect primary pathologic process so rarely results in control of disease when used alone
- immunosuppression
  - steroids are mainstay of treatment (70-80% remission rate)
  - azathioprine, cyclophosphamide, and mycophenolate as adjuncts or as steroid sparing therapy
- short-term immunomodulation (for crises)
  - IVIG and plasmapheresis

**Prognosis**
- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

**Lambert-Eaton Myasthenic Syndrome**

**Etiology and Pathophysiology**
- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcinoma of the lung

**Signs and Symptoms**
- see Table 21
- weakness of skeletal muscles without sensory or coordination abnormalities
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and oculomotor muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

**Investigations**
- edrophonium test (see Myasthenia Gravis, N40) → no response
- EMG
  - rapid (>10 Hz) repetitive stimulation → incremental response
  - post-exercise facilitation → an incremental response with exercise
  - screen for malignancy, especially small cell lung cancer

**Figure 22. Myasthenia gravis**

**Figure 23. Lambert-Eaton myasthenic syndrome (LEMS)**
Treatment
- tumour removal
- acetylcholine modulation
  - increased acetylcholine release (3,4-diaminopyridine)
  - decreased acetylcholine degradation (pyridostigmine)
- immunomodulation
  - steroids, plasmapheresis, IVIG

Botulism

Etiology and Pathophysiology
- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which is found in soil and water throughout the world
- bacteria can enter the body through wounds or by ingesting improperly preserved foods
- infantile botulism is the most common form, and is usually from ingestion of honey or corn syrup

Signs and Symptoms
- occur 6-48 h after ingestion
- difficulty with convergence, ptosis, paralysis of extraocular muscles
- dilated, poorly reactive pupils
- other autonomic dysfunction: jaw weakness, dysarthria, dysphagia
- spreads to trunk and limbs
  - abdominal cramps with nausea and vomiting
  - symmetric weakness with paralysis and absent/decreased deep tendon reflexes
  - anticholinergic symptoms: dry mouth, constipation, urinary retention
- rarely respiratory distress, potentially advancing to respiratory failure
  - pattern of paresis often starts with GI symptoms (constipation, early satiety), then paresis of extraocular muscles, then dysphagia, then limbs/respiratory involvement; all associated with dry mouth

Investigations
- blood test for toxin
- stool culture

Treatment
- botulinum anti-toxin – good prognosis with prompt treatment
- supportive therapy as required

Myopathies

MELAS = mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF = mitochondrial encephalomyopathy with ragged red fibres

Polymyositis/Dermatomyositis

- see Rheumatology, RH15

Myotonic Dystrophy

Etiology and Pathophysiology
- unstable trinucleotide (CTG) repeat in DMK gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms
- autosomal dominant

Epidemiology
- most common adult muscular dystrophy
- prevalence 3-5/100,000

Signs and Symptoms
- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myostonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1st heart block; atrial arrhythmias)
  - respiratory: hypoventilation 2nd to muscle weakness
  - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
  - other: DM, infertility, testicular atrophy
- EMG: subclinical myotonia – long runs with declining frequency and amplitude

Treatment and Prognosis
- no cure, progressive, death usually around 50 yr
- management of myotonia: phenytoin

Duchenne and Becker Muscular Dystrophy

- see Pediatrics, P45
Pain Syndromes

Approach to Pain Syndromes

Definitions
• nociceptive pain: pain arising from normal activation of peripheral nociceptors
• neuropathic pain: pain arising from direct injury to neural tissue, bypassing nociceptive pathways
• spontaneous pain: unprovoked burning, shooting, or lancinating pain
• paresthesia: spontaneous abnormal non-painful sensation (e.g. tingling)
• dyesthesias: evoked pain with inappropriate quality or excessive quantity
• loss of sensation
• hypesthesias: loss of pain sensation
• hyperalgesia: an exaggerated pain response to a noxious stimulus
• allodynia: a dyesthetic response to a non-noxious stimulus

Non-Pharmacological Management
• physical (PT, acupuncture, chiropractic manipulation, massage)
• psychoeducational (CBT, family therapy, education, psychotherapy)

Medical Pain Control
• combination multi-modal therapy is important
• primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
• adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxybenzamine), \( \alpha_2 \)-adrenergic agonists (clonidine)

Surgical Pain Control
• peripheral ablation: nerve blocks, facet joint denervation
• direct delivery: implantable morphine pump
• central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
• DBS or dorsal column stimulation

Neuropathic Pain

Definition
• pain resulting from a disturbance of the central or peripheral nervous system

Symptoms and Signs
• hyperalgesia/allodynia
• subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness (i.e. stocking/sock distribution)
• can be spontaneous or stimulus evoked
• distribution may not fall along classical neuro-anatomical lines
• associated issues: sleep difficulty, anxiety/stress/mood alteration

Causes of Neuropathic Pain
• sympathetic
  • complex regional pain syndrome
• central: abnormal CNS activity
  • phantom limb, post spinal cord injury, post stroke, MS
• non-sympathetic: damage to peripheral nerves
• systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis
• nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
• infectious: post-herpetic, HIV
• trauma/compression: nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy

Treatment
• identify/treat underlying cause
• pharmacotherapy
  • Stepwise approach (Canadian Pain Society, 2007): TCA, anticonvulsants, SNRI, topical lidocaine, long acting opiate (caution), tramadol
  • other: capsaicin cream, intrathecal opioid, or clonidine, botulinum toxin injection, nerve block
• common non-pharmacologic therapies
  • neuropsychiatry: CBT, psychotherapy
  • rehabilitation: physiotherapy
  • complementary and alternative medicine: acupuncture, meditation, massage therapy, traditional Chinese medicine
• surgical therapies: dorsal column neurostimulator, DBS (thalamus)
Trigeminal Neuralgia

Clinical Features
• recurrent episodes of sudden onset, excruciating unilateral paroxysmal shooting “electric” pain in trigeminal root territory (V3>V2>V1)
• may have normal sensory exam
• pain lasts seconds/minutes over days/weeks; may remit for wk/mo
• triggers: touching face, eating, talking, cold wind, shaving, applying make-up

Etiology
• classic TN: idiopathic
• secondary TN: compression by tortuous blood vessel (superior cerebellar artery), cerebellopontine angle tumour (5%), MS (5%)

Epidemiology
• F>M; usually middle-aged and elderly

Diagnosis
• clinical diagnosis
• investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  ▪ MRI to rule out structural lesion, MS, or vascular lesion

Treatment
• first line: carbamazepine or oxcarbazepine
• second line: baclofen or lamotrigine
• narcotics not generally recommended
• if medical treatment fails: trigeminal ganglion percutaneous technique, gamma knife, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression

Postherpetic Neuralgia

Clinical Features
• pain persisting in the region of a cutaneous outbreak of herpes zoster
• constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
• distribution: thoracic, trigeminal, cervical > lumbar > sacral
• associated impaired sleep, decreased appetite, decreased libido

Etiology and Pathogenesis
• destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

Epidemiology
• incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
• risk factors: older age, greater acute pain, greater rash severity

Prevention
• varicella zoster vaccine (Varivax®) in childhood reduces incidence of varicella zoster
• herpes zoster vaccine (Zostavax®) reduces incidences of shingles, PHN, and other herpetic sequel (currently recommended in Canada for those >60 yr old)

Treatment
• medical: TCA (i.e. amitriptyline), anti-convulsants (i.e. pregabalin, gabapentin), analgesia (i.e. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  ▪ early treatment of acute herpes zoster with antivirals (acyclovir; longer-acting famciclovir and valacyclovir more effective)
  ▪ treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
• surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

Painful Diabetic Neuropathy

• see Endocrinology, E13

Approach
• determine if pain is neuropathic or vascular
• more likely neuropathic if
  ▪ feet > calves
  ▪ sharp/tingling pain
  ▪ pain present at rest and improves with walking
Treatment
- Level A: pregabalin
- Level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

**Complex Regional Pain Syndromes**

**Clinical Features**
- presence of an initiating noxious event (MI, stroke)
- continuing pain, allodynia, or hyperalgesia with pain disproportionate to inciting event
- evidence during the course of symptoms of edema, changes in skin blood flow or abnormal vasomotor activity
- absence of conditions that would otherwise account for degree of pain and dysfunction
- other features can include edema, osteoporosis, hyperhidrosis, hair loss, fascial thickening

**Classification**
- CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

**Investigations**
- trial of differential neural blockade may be helpful in diagnosis
- autonomic testing (evidence of sympathetic dysfunction)
- bone scan, plain radiography, MRI

**Prevention**
- early mobilization after injury/infarction

**Treatment**
- goal of treatment: to facilitate function
- conservative treatment: education, support groups, PT/OT, smoking cessation
- medical: topical capsaicin, TCA, NSAID, tender point injections with corticosteroid/lidocaine, gabapentin/pregabalin/lamotrigine, calcitonin or bisphosphonates, oral corticosteroids
- surgical: paravertebral sympathetic ganglion blockade
- refer to pain management clinic

**Headache**

- see Emergency Medicine, ER23 and Family Medicine, FM33

**Clinical Approach**
- history
  - pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/cough/Valsalva)
  - associated symptoms: visual changes, change in mental status, nausea/vomiting, fever, meningismus, photophobia, phonophobia, TMJ popping/clicking, jaw claudication, neurological symptoms
  - precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, CCBs, NSAIDs, anticoagulants), PMH, FHx
  - red flags (possible indications for CT scan/further investigation): new-onset headache (especially if age <5 or >50), quality worse/different than previous headaches, sudden and severe (‘thunderclap’), immunocompromised, fever, focal neurological deficits, trauma
- physical exam
  - vitals (including BP and temp), Kernig’s/Brudzinski’s, MSK examination of head and neck
  - HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
  - full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
  - red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

**Classification**
- primary
  - tension, migraine, cluster, other autonomic cephalgias
- secondary
  - cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN or pseudotumour cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

Acute and Preventive Pharmacologic Treatment of Cluster Headache

Neurology 2012;75:463-473

Study: Meta-analysis of prospective, double-blind, RCTs of pharmacologic agents for prevention or treatment of CH.

Results: 27 trials were included. Sumatriptan 6 mg SC, zolmitriptan nasal spray 5-10 mg, and 100% oxygen 6-12 L/min received Level A recommendation for acute treatment. For prevention, Level B recommendations were given for intranasal xenon oxide 100 μg daily and subcutaneous steroids injections.

Conclusion: Sumatriptan, zolmitriptan, and mid flow oxygen are effective acute treatments for CH.

Anticonvulsants in Migraine Prophylaxis

Cochrane DB Syst Rev 2009;3:CD003226

Study: Meta-analysis of prospective, controlled trials of anticonvulsant drugs in migraine headache prophylaxis.

Results: Twenty-three studies (n=2,927) were included. Anticonvulsants reduce migraine frequency by 3.3 attacks per 28 days compared to placebo and double the number of patients for whom migraine frequency is reduced by 50% (RR=2.25, NNT=3.9). Valproate and topiramate are better than placebo, while clobazam, acetazolamide, lamotrigine, and vigabatrin are not. Clinically important adverse events were associated with valproate and topiramate with NNT 7.0-18.8 and 2.4-31.2, respectively.

Conclusion: Anticonvulsants are effective in reducing migraine frequency and reasonably well-tolerated. Valproate and topiramate are the two most studied but further studies of head-to-head comparisons between agents is needed.

The Rational Clinical Examination: Does this Patient with Headache have a Migraine or Need Neuroimaging?

JAMA 2006;296:1274-1283

Does this patient with headache have a migraine? The most useful panel of questions for diagnosing migraine is summarized by the POUNDing mnemonic:

P – Pulsatile quality
O – Onset – duration of 4-72 h
D – Disturbing intensity
U – Unilateral location
N – Nausa or vomiting
D – Disability intensity

The LR for definite or possible migraine diagnosis varies with the number of features present: with ≥4, 3 and ≥2 features, the LRs are 24 (1.5-388), 3.5 (1.3-9.2), and 0.41 (0.32-0.52), respectively.

Conclusion: Anti-convulsants are effective in reducing migraine frequency and reasonably well-tolerated. Valproate and topiramate are the two most studied but further studies of head-to-head comparisons between agents is needed.

Does this patient with headache need neuroimaging? In patients with new or changed headache the prevalence of significant intracranial pathology is 32% (24-42%), and in those presenting with thunderclap headache the prevalence is 43% (20-64%).

Several individual clinical features were found to be predictive of significant intracranial pathology:

Symptom
Cluster type headache
Abnormal neurological exam
Unilateral type headache
Headache with aura
Headache with vomiting

N/V
Polyphasia rheumatica
Visual loss
Headache with vomiting

Conclusion: New or changed headache requires neuroimaging. In patients presenting with thunderclap headache or headache with aura, neuroimaging is warranted.

Migraine Headaches

Definition (Common Migraine)

• ≥5 attacks fulfilling each of the following criteria
  ▪ 4–72 h duration
  ▪ 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  ▪ 1 of the following: nausea/vomiting, photophobia/phonophobia/osmophobia

Epidemiology

• 18% females, 6% males; frequency decreases with age (especially at menopause)

Etiology and Pathophysiology

• theories of migraine etiology
  ▪ depolarizing wave of “cortical spreading depression” across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibres
  ▪ possible association with vasoconstriction/dilation
  ▪ significant genetic contribution

• triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrates (e.g. processed meats)

Signs and Symptoms

• stages of uncomplicated migraine
  i. prodrome (hours to days before headache onset)
  ii. aura
  iii. headache (see Table 23 for description of typical headache)
  iv. postdrome
  • aura
    ▪ fully reversible symptom of focal cerebral dysfunction lasting <60 min
    ▪ examples: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
  • prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
  • classification of migraines
    ▪ common migraine: no aura
    ▪ classic migraine: with aura (headache follows reversible aura within 60 min)
    ▪ complicated migraine: with severe/persistent sensorimotor deficits
      ▪ examples
        – basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness)
        – hemiplegic/hemisensory migraine
        – ophthalmoplegic migraine
    ▪ acephalic migraine (i.e. migraine equivalent): aura without headache

Treatment

• avoid triggers
• mild to moderate migraine
  ▪ 1st line: NSAIDs (ibuprofen, naproxen)
  ▪ moderate to severe migraine
    ▪ triptans (most effective), ergots (dihydroergotamine, DHE)
    ▪ migraine prophylaxis: anticonvulsants (divalproex, topiramate, gabapentin), TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIA and seizures)

“If patient presents to ED with severe migraine and N/V – consider treating with IV anti-emetics (chlorpromazine, prochlorperazine)

“Menstrual Migraine” Subtype
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding

Pharmacological Treatments for Acute Migraine

Pain 2002;97:247-257

Study: Meta-analysis of 54 double-blind, placebo-controlled RCTs of pharmacologic treatment of acute migraine of moderate to severe intensity (21,022 patients in total).

Data Extraction: Number of patients, dosing regimen, details of study design, timing or type of rescue medication. Outcomes include headache relief at 1 and 2 h, freedom from pain at 2 h, sustained relief for 24 h, and adverse effects within 24 h.

Main Results: Data were available for 9 oral medications, 2 intranasal medications, and subcutaneous sumatriptan. For H/A relief at 2 h, all interventions were effective except Celebrex®, with NNTs ranging from 2.0 for sumatriptan 6 mg SC to 5.4 for naratriptan 2.5 mg. The lowest NNT for oral medication was 2.6 for eletriptan 80 mg. For patients pain free at 2 h, the lowest NNT was 2.1 for sumatriptan 6 mg SC, with the lowest NNT for oral medication being 3.1 for rizatriptan 10 mg. For sustained relief over 24 h NNT ranged from 2.8 for eletriptan 80 mg to 8.3 for naratriptan 5 mg. Side effects could not be analyzed systematically. There were no drug-to-drug comparisons.

Conclusion: Overall, most treatments were effective. Subcutaneous sumatriptan and oral triptans were most effective.

A prophylactic agent is recommended only if migraine attacks are severe enough to cause impairment of a patient’s quality of life or if a patient has >3 migraines/mo that have not responded adequately to treatment

Neurology 2000;55:754-763
Sleep Disorders

Overview of Sleep

Definition
- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many elderly have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture
- polysomnogram (PSG) measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 26. Sleep Stage Characteristics

<table>
<thead>
<tr>
<th>EEG</th>
<th>EOG</th>
<th>Muscle Tone</th>
<th>Other Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Waking State</td>
<td>Alpha waves: high frequency (8-13 Hz), low voltage</td>
<td>Rapid, blinking</td>
<td>High</td>
</tr>
<tr>
<td>Stage N1 (~5%)</td>
<td>Alpha waves: high frequency (8-13 Hz), low voltage</td>
<td>Slow, roving eye movements</td>
<td>High, but gradually dropping Marker for very light quality sleep or sleep disruption</td>
</tr>
<tr>
<td>Stage N2 (~50%)</td>
<td>K complexes (high voltage negative and positive discharges) with sleep spindles (11-16 Hz)</td>
<td>Still</td>
<td>High</td>

</table>

Disturbances of Alertness and Sleep

Coma
- see Neurosurgery, NS34

Insomnia
- definition/criteria
  - difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep
- types
  - sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
- secondary causes
  - psychiatric disorders (80% of psychiatric patients): anxiety and depression (see Psychiatry, PS10)
  - neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
  - sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
  - medical conditions: pregnancy, cardiorespiratory (COPD/HF), GERD, pain (arthritis, fibromyalgia, cancer)
  - drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal
- treatment
  - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT

Drug Effects on Wakefulness and Sleep
- Antihistamines associated with increased sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increases wakefulness
- Benzodiazepines reduce slow wave sleep
- Antidepressants (TCA/MAOI/SSRI) reduce REM, prolong REM latency
- Alcohol may hasten sleep onset but associated with increased arousals
Sleep Apnea
- **definition**
  - disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)
- **epidemiology**
  - >2-4% of the population
  - increasing obesity
  - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)
- **types**
  - obstructive sleep apnea: see *Respirology*, R31
  - central sleep apnea: no effort to breathe over 10 s
  - mixed apnea: starts as central, but eventually becomes obstructive
- **etiology of central apnea:** heart failure, opiates, brainstem pathology, myotonic dystrophy
- **diagnosis:** apnea hypopnea index (AHI) or respiratory disturbance index (RDI) should be <5 in the normal state
- **treatment:** conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety

Restless Leg Syndrome and Periodic Limb Movement in Sleep
- **definition**
  - urge to move accompanied by uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night
  - RLS refers to sensation
  - PLMS refers to the manifestation
- **epidemiology:** 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS
- **etiology:** central (spasticity), peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use
- **treatment**
  - underlying contributors (iron and B12 supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
  - NOT recommended: Sinemet®, causes augmentation

Narcolepsy
- **definition/clinical features:** excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic), sleep paralysis (unable to move upon wakening), hypnagogic hallucinations (vivid dreams or hallucinations at sleep onset)
- **epidemiology:** prevalence 1:2,000, onset in adolescence/early adulthood; life-long disorder
- **etiology:** presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial
- **diagnosis:** based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps
- **treatment**
  - sleep hygiene and scheduled brief naps, restricted driving
  - alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
  - anticitaplectic: TCAs, SSRIs, sodium oxybate

Parasomnias
- **definition/clinical features:** unusual behaviours in sleep with clinical features appropriate to stage of sleep
- **etiology:** in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep disordered breathing
- **diagnosis:** clinical history in children, polysomnography in adults to exclude nocturnal seizures
- **treatment:** behavioural management (safety, adequate sleep); clonazepam for REM sleep behaviour, tonsillectomy if appropriate in children

Circadian Rhythm
- **definition/clinical features:** abnormalities based on time of day rather than sleep (i.e. jet lag, shift work)
- **diagnosis:** clinical history

CNS Infections
- see *Infectious Diseases*, ID18

Spinal Cord Syndromes
- see *Neurosurgery*, NS27
Stroke

Terminology

- **stroke**: sudden onset of neurological deficits of a vascular basis with infarction of CNS tissue
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- **TIA**: sudden onset of neurological deficits of a vascular basis without infarction (i.e. no imaging evidence of stroke)

Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

1. Ischemic
   - **arterial thrombosis**: thrombus formation in artery (local/in situ)
     - *large vessel*: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
       - mechanisms
         - insufficient blood flow beyond lesion (hemodynamic stroke)
         - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
     - *small vessel/lacunar*
       - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
       - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
   - **cardioembolic**: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
     - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
   - **systemic hypoperfusion** (global cerebral ischemia)
     - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
     - primarily affects watershed areas (between the major cerebral arterial territories)

2. Hemorrhagic
   - **intracerebral hemorrhage**
     - mechanisms
       - hypertensive (most common): rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage
         - most common sites: putamen, thalamus, cerebellum, and pons
       - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaine or amphetamines)
   - **subarachnoid hemorrhage** see Neurosurgery, NS18

Stroke Syndromes According to Vascular Territory

- **ACA**: contralateral leg paresis, sensory loss, cognitive deficits (e.g. apathy, confusion, and poor judgment)
- **MCA**: proximal occlusion involves
  1. contralateral weakness and sensory loss of face and arm
  2. cortical sensory loss
  3. may have contralateral homonymous hemianopia or quadrantanaopia
  4. if dominant (usually left) hemisphere: aphasia
  5. if non-dominant (usually right) hemisphere: neglect
  6. eye deviation towards the side of the lesion and away from the weak side
- **PCA**
  1. contralateral hemianopia or quadrantanaopia
  2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  3. thalamic findings: sensory loss, amnesia, decreased level of consciousness
  4. if bilateral: cortical blindness or prosopagnosia
- **basilar artery** (locked-in syndrome):
  1. quadriparesis
  2. dysarthria
  3. impaired eye movements
- **PICA** (lateral medullary or Wallenberg syndrome): ipsilateral ataxia, ipsilateral Horner’s, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, nausea/vomiting, dysphagia, dysarthria, hicups

Hypertension Encephalopathy

Acute severe HTN (typically dBP >130 or sBP >200) can cause hypertensive encephalopathy – abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances, and change in LOC

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can also have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with MRV or CTV. Treatment is typically anticoagulation with heparin initially, then transition to warfarin

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction

Blood work should only delay treatment if: patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

Suspect an alternate diagnosis if: fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after the onset of stroke
- **medial medullary infarct** (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness

- **lacunar infarcts (deep hemispheric white matter)**
  - pure motor hemiparesis (posterior limb of internal capsule): contralateral arm, leg, and face
  - pure sensory loss (thalamic): hemisensory loss
  - ataxic hemiparesis: ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome: dysarthria, facial weakness, dysphagia, mild hand weakness and clumsiness

---

**Assessment and Treatment of Ischemic Stroke**

**General Assessment**
- ABCs, full vital sign monitoring, capillary glucose, (Accu-Chek®), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
- level of consciousness (knows age, month, obeys commands), dysarthria, anomia (cannot name objects), gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- history
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- investigations
  - non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
  - ECG: to rule out atrial fibrillation (cardioembolic cause)
  - CBC, electrolytes, creatinine, PTT/INR, blood glucose
- imaging (i.e. CT) signs of stroke
  - loss of cortical white-grey differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense MCA sign

**Aspect Score:** 10-point quantitative score to assess ischemic changes on CT scan
- 10/10 is normal and <4/10 signifies high risk of bleed with rtPA
- Subtract 1 point for each of following structures if abnormal within the ischemic hemisphere: caudate, lentiform, insula, internal capsule, MCA 1, 2, 3, 4, 5, 6 regions

---

The National Institute of Health Stroke Scale (NIHSS) is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time. The scale uses 11 items that evaluate:
- Level of consciousness
- Visual system
- Motor system
- Sensory system
- Language abilities

Scoring (x/42):
- 0 = no stroke
- 1-4 = mild stroke
- 5-15 = moderate stroke
- 15-20 = moderate to severe stroke
- 21-42 = severe stroke

rtPA is typically considered if score ≥6, but some stroke neurologists will administer rtPA with lower NIH stroke scale scores
ACUTE STROKE MANAGEMENT

1. Thrombolysis
   • rtPA (recombinant tissue plasminogen activator)
   • given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use:
     • indications: based on NIH Stroke Scale (NIHSS – see sidebar)
     • contraindications: see sidebar

2. Anti-Platelet Therapy
   • give at presentation of TIA or stroke if rtPA not received
   • antplatelet agents
     • ASA: recommended dose 81 mg chewed
       • if patient intolerant to ASA, use other antiplatelet agent (i.e. clopidogrel)

3. Acute Anti-Coagulant Therapy
   • for patients with TIA or stroke and atrial fibrillation if rtPA not received
     • recommend IV heparin (or ensuring INR between 2-3 if already anticoagulated on warfarin)

4. Intra-arterial Thrombectomy by Interventional Radiology

Other Acute Management Issues
   • avoid hyperglycemia which can increase the infarct size
   • lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
   • avoid hyperglycemia which can increase the infarct size

Blood Pressure Control
   • do NOT lower the blood pressure unless the HTN is severe
     • antihypertensive therapy is withheld for at least 5 d after thromboembolic stroke unless
       sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection
     • acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
     • most patients with an acute cerebral infarct are initially hypertensive and their BP will fall spontaneously within 1-2 d
     • IV labetalol first-line if needed

Etiological Diagnosis
   • further investigations
     • additional neuroimaging (MRI)
     • vascular imaging: CTA/MRA/carotid dopplers
     • cardiac tests: echocardiogram, Holter monitoring
     • correct etiological diagnosis is critical for appropriate secondary prevention strategies

Primary and Secondary Prevention of Ischemic Stroke

Anti-Platelet Therapy
   • primary prevention
     • current evidence has not firmly established a protective role for antiplatelet agents for
       low-risk patients without a prior stroke/TIA
   • secondary prevention
     • ASA is the initial antiplatelet of choice for stroke prevention
     • other agents (generally reserved for those who suffer cerebrovascular symptoms while on ASA
       or if unable to tolerate ASA)
       • Aggrenox® (ESPRIT trial)
       • clopidogrel (CAPRIE trial)

Carotid Stenosis
   • primary prevention (asymptomatic)
     • carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
   • secondary prevention (previous stroke/TIA in carotid territory)
     • carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%),
       and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET
       trial), see Vascular Surgery: VS8
according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI.

**Atrial Fibrillation**
- primary and secondary prevention with antiocoagulation
  - classically risk stratification used CHADS² score, but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be antiocoagulated
    - 0 (very low risk): antiplatelet
    - 1 (low risk): antiocoagulant or antiplatelet – patient specific decision
    - >2 (mod-high risk): antiocoagulant
  - antiocoagulation therapy
    - warfarin (titrate to INR 2-3)
    - dabigatran (110 or 150 mg PO bid), apixaban (2.5 or 5 mg PO bid) or rivaroxaban (15 or 20 mg PO daily) may be alternatives to warfarin, but should be used cautiously due to lack of a reversal agent should bleeding occur

**Hypertension**
- primary prevention
  - targets: BP <140/90 (or <130/80 for diabetics or renal disease)
  - ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
  - ACEI reduce the risk of stroke beyond their antihypertensive effect
- secondary prevention
  - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

**Hypercholesterolemia**
- primary prevention
  - statins reduce the risk of stroke in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
  - statins reduce risk of subsequent stroke – best evidence is for high dose atorvastatin (SPARCL trial) but lower doses may be more appropriate if patient cannot tolerate high dose

**Diabetes**
- ideal management: HbA1c <7%, fasting blood glucose between 4 and 7

**Smoking**
- primary prevention
  - smoking increases risk of stroke in a dose-dependent manner
- secondary prevention
  - after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

**Physical Activity**
- regular physical activity is an important lifestyle measure in stroke prevention and its beneficial effect has a dose-related response in terms of intensity and duration of activity

**Stroke Rehabilitation**
- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

---

**Cerebral Hemorrhage**

**Investigations**
- general investigations, see *Assessment and Treatment of Ischemic Stroke*, N51
- further investigations
  - LP (if suspect subarachnoid hemorrhage despite negative CT)
  - may require cerebral angiogram if suspect aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion
Treatment
• medical
  • anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA
guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is
safe and appropriate management (target sBP 140-160 systolic)
  • ICP lowering medical management (if necessary): see Neurosurgery, NS7
• surgical: see Neurosurgery, NS20

Neurocutaneous Syndromes
• see Pediatrics, P86

Multiple Sclerosis
Definition
• a chronic inflammatory disease of the CNS characterized by relapsing remitting, or progressive
  neurologic symptoms due to inflammation, demyelination, and axonal degeneration

Clinical Patterns of MS
• relapsing remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing
  (PRMS) 5%, secondary progressive (SPMS)
• benign MS (BMS): retrospective diagnosis made after 15 years of mild disease, with no evidence
  of worsening (in functional ability and MRI)
• most RRMS goes on to become SPMS

MS Variants
• Devic’s = neuromyelitis optica (NMO): severe optic neuritis and extensive transverse myelitis
  extending >3 vertebral segments (NMO antibody positive)
• clinically isolated syndrome (CIS): single MS-like episode, which may progress to MS
• tumefactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
• fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal
damage, inflammation, and necrosis
• pediatric MS: onset of MS before the age of 18
  • epidemiology: rare (1.35-2.5 per 100,000 children)
  • presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome
    or symptoms of encephalopathy compared to adults
  • course: 98% have RRMS
  • diagnosis and treatment similar to adult MS
• differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of
  white matter lesion, rule out ADEM, optic neuritis, transverse myelitis, neuromyelitis optica,
  CNS malignancies, leukodystrophies, and mitochondrial disease
• acute disseminated encephalomyelitis (ADEM): monophasic demyelinating disorder with
  multifocal neurologic symptoms seen mainly in children often following infection or vaccination

Etiology
• genetic
  • polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  • 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
• environmental
  • MS is more common in regions with less sun exposure and lower stores of vitamin D
    (Europe, Canada, US, New Zealand, SE Australia)
  • MS has also been linked to certain viruses (EBV is associated with MS)

Epidemiology
• onset 17-35 yr; F:M = 3:1
• PPMS occurs in an older population with F=M

Diagnosis
• dissemination in space and in time as based on the revised McDonald criteria
  • dissemination in space: clinical evidence of 2 or more lesions, or three of
    (1 gadolinium enhancing or 9 T2 lesions), (1 infratentorial lesion), (1 juxtacortical lesion),
    (3 periventricular lesions)
Clinical Features
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- **Lhermitte's sign**: flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- **Uthoff’s phenomenon**: worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual findings of new onset, visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4 to 0.6 relapses/yr, but higher disease activity in 1st yr of disease

Investigations
- MRI: demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
  - Dawson's fingers: periventricular lesions extending into corpus callosum
  - cranial MRI is more sensitive than spinal MRI
- **CSF**: oligoclonal bands in 90%, increased IgG concentration
- **evoked potentials (visual/auditory/somatosensory)**: delayed but well-preserved wave forms

Treatment
- **acute treatment**: methylprednisolone 1,000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids may consider plasma exchange
- disease modifying therapy (DMT)
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: interferon-β (injection: Betaseron®, Avonex®, Rebif®), glatiramer acetate (injection: Copaxone®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion)
  - new oral agents: fingolimod (Gilenya®)
  - indications for fingolimod: newly diagnosed patients with active RRMS who prefer oral treatment despite increased risks or those intolerant of first line therapies
  - CIS: early treatment with interferons may delay potential second attack
  - RRMS: DMT reduces rate of relapse by about 30%
  - PPMS/SPMS: no proven efficacy of DMTs
- symptomatic treatment
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantadine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil (Viagra®), tadalafil (Cialis®), vardenafil (Levitra®, Staxyn®)
- **education and counseling**: MS Society, support groups, psychosocial issues

Prognosis
- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

**Chronic Cerebrospinal Venous Insufficiency (CCSVI)**
A theory proposed in 2008 describing abnormal venous blood flow in patients with MS; while some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

**The Expanded Disability Status Scale (EDSS)**
Is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

**Oral Fingolimod or Intramuscular Interferon for Relapsing Multiple Sclerosis**
*NEJM* 2010;362:402-415
Method: Multicentre double-blind RCT.
Population: 1,292 patients with relapsing-remitting MS and at least one relapse.
**Intervention**: Oral fingolimod at 0.5–1.25 mg or 30–120 IM interferon (IFN-
**Outcomes**: Annualized relapse rate over 1 yr; lesions on T2-weighted MRI.
**Results**: Annualized relapse rate was lower in both groups receiving fingolimod compared to interferon: 0.30 (95% CI 0.19–0.26) with 1.25 mg fingolimod, 0.18 (95% CI 0.12–0.21) with 0.5 mg fingolimod, 0.33 with interferon (95% CI 0.26–0.42; p < 0.001). MRI findings also showed greater reduction of lesions in fingolimod-treated patients. Progression of disability was unchanged. Side effects included severe infections like HSV encephalitis, disseminated VZV, other HSV infections, and skin cancer.
**Conclusions**: Oral fingolimod is superior to interferon-β injections in reducing relapses and MRI lesion load in patients with MS.

**Recombinant Interferon Beta or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis**
*Cochrane DB Syst Rev* 2008;2:CD005278
Study: Meta-analysis of RCTs of clinically isolated syndrome (CIS) patients treated with immunomodulatory drugs.
**Primary Outcome**: Proportion of patients converting to clinically definite MS and adverse effects.
**Results**: Three trials (n = 1,160) tested the efficacy of interferon (IFN-β) and no trial tested glatiramer acetate (GA). A pooled odds ratio (OR) of 0.53 (95% CI 0.40–0.71; p < 0.001) for patients on IFN vs. placebo at 1 yr. Two year follow-up odds ratio was 0.52 (95% CI 0.38–0.70; p < 0.001). There was no significant increase in adverse events for those on IFN-β.
**Conclusions**: IFN-β treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.

</table>
ICP/Volume Relationship

- adult skull is rigid with a constant intracranial volume
- contents (CSF, blood, brain) are incompressible (Monro-Kellie doctrine)
- increase in one constituent/space-occupying lesion = 1) increase in ICP, 2) require redistribution of CSF, blood, or brain
- however, ICP does not rise initially due to compensatory mechanisms
  - immediate: displacement of CSF to lumbar theca, displacement of blood from venous sinuses
  - delayed: displacement of ECF or ICF, displacement of brain tissue into compartments under less pressure (herniation)
- once compensation is exhausted, ICP rises exponentially

Cerebral Blood Flow

- brain receives about 15% of cardiac output (~750 mL/min)
- CBF depends on cerebral perfusion pressure (CPP) and cerebral vascular resistance (CVR)
- normal CPP >50 mmHg in adults
- cerebral autoregulation maintains constant CBF by compensating for changes in CPP, unless:
  - high ICP such that CPP <60 mmHg
  - MAP >150 mmHg or MAP <50 mmHg
  - brain injury: e.g. SAH, severe trauma

ICP Measurement

- normal ICP <15 mmHg (8-18 cmH2O) for adult, 3-7 mmHg (4-9.5 cmH2O) for child; varies with patient position
  - moderate elevation: increase in mean pressure >20 mmHg
  - severe elevation: increase in mean pressure >40 mmHg
- waveform: comprised of respiratory and cardiac pulsations (Traube-Hering waves); the amplitude increases with ICP
  - β-waves: coarse, variably increased amplitude, frequency ½-2/min, often related to respiration
  - plateau waves: elevation of ICP over 50 mmHg lasting 5-20 min, precursor of further deterioration

Acute Monitoring

- lumbar puncture (LP)
- intraventricular catheter/ventriculostomy/external ventricular drain (EVD) ("gold standard", also permits therapeutic drainage of CSF to decrease ICP)

Chronic Monitoring

- fibreoptic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Elevated ICP

Etiology

- intracranial space-occupying lesion
  - tumour
  - pus
  - blood (trauma → hematoma [most common], subarachnoid hemorrhage)
  - depressed skull fracture
  - foreign body
- increased intracranial blood volume
  - vasodilatation (increased pCO₂/decreased pO₂/decreased extracellular pH, e.g. hypoventilation)
  - venous outflow obstruction (venous sinus thrombosis, superior vena cava syndrome, space-occupying lesion)
  - cranial dependency
- cerebral edema
  - vasogenic (vessel damage, e.g. hypertensive encephalopathy, tumour)
  - cytotoxic (tissue/cell death, e.g. hypoxia, brain injury)
  - osmotic (acute hyponatremia, hepatic encephalopathy)
• hydrocephalus
  ▪ obstructive: acquired aqueductal stenosis
  ▪ non-obstructive: decreased CSF absorption with SAH
• pseudotumour cerebri (idiopathic intracranial HTN)
• impaired autoregulation (hypotension, HTN, brain injury)
• status epilepticus (chronic seizure resulting in brain edema)

Clinical Features
1. Acute Elevated ICP
• H/A: worse in the morning, aggravated by stooping, and bending
• N/V
• decreased LOC if ICP = dBP, or midbrain compressed
• drop in GCS = best index to monitor progress and predict outcome of acute intracranial process (see Neurotrauma, NS29)
• papilledema ± retinal hemorrhages (may take 24-48 h to develop)
• abnormal extra-ocular movements (EOM)
  ▪ CN VI palsy: often falsely localizing (causative mass may be remote from nerve)
  ▪ upward gaze palsy (especially in children with obstructive hydrocephalus)
• herniation syndromes
• focal signs/symptoms due to lesion

2. Chronic Elevated ICP
• H/A postural: worsened by coughing, straining, and bending over
• morning/evening H/A → vasodilatation due to increased CO₂ with recumbency
• visual changes
  ▪ due to papilledema
  ▪ enlarged blind spot, if advanced → episodic constrictions of visual fields (“grey-outs”)
  ▪ optic atrophy/blindness
  ▪ differentiate from papillitis (usually unilateral with decreased visual acuity)
• decreased level of consciousness

Investigations
• patients with suspected elevated ICP require an urgent CT/MRI
• ICP monitoring where appropriate

</tbody>
</table>

Figure 6. Herniation types

© Heidi Maj
**Treatment of Elevated ICP**

- CT or MRI to identify etiology, assess for midline shift/herniation
- treat primary cause (i.e. remove mass lesions, ensure adequate ventilation)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- goals: keep ICP <20 mmHg, CPP >65 mmHg, MAP >90 mmHg

**Conservative Measures**

- elevate head of bed at 30°, maintain neck in neutral position → increases intracranial venous outflow with minimal effect on arterial pressure
- prevent hypotension with fluid and vasopressors, dopamine, norepinephrine prn
- ventilate to normocarbia (pCO₂ 35-40 mmHg) → prevents vasodilatation
- oxygen to maintain pO₂ >60 mmHg → prevents hypoxic brain injury
- osmolar diuresis (mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6h to serum osmolarity of 315-320)
  - can give rapidly, acts in 15-30 min, must maintain sBP >90 mmHg
  - corticosteroids → decrease edema over subsequent days around brain tumor, abscess, blood
  - no proven value in head injury or stroke

**Aggressive Measures**

- sedation (“light” e.g. barbiturates/codeine → “heavy” e.g. fentanyl/MgSO₄)
- paralysis with vecuronium → reduces sympathetic tone, reduces HTN induced by muscle contraction
- hyperventilate to pCO₂ 30-35 mmHg
  - use for brief periods only – also results in decreased cerebral blood flow
- drain 3-5 mL CSF via ventricles, assess each situation independently
- insert EVD (if acute) or shunt
- barbiturate-induced coma induced with pentobarbital to reduce cerebral blood flow and metabolism (10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion)
  - decreases mortality, but no improvement in neurological outcome
- decompressive craniectomy is a last resort
- no role for the use of hypothermia in head injury

**Hydrocephalus**

- hydrocephalus in children, see *Pediatric Neurosurgery*, NS35

**Definition**

- accumulation of excess CSF in the brain
- CSF: produced by choroid plexus lateral ventricles
- total volume ~120 mL, including 30 cc within ventricular system, remainder in SA space
- flow: lateral ventricle → foramina of Luschka (lateral) and Magendie (medial) → subarachnoid space
- re-absorbed by arachnoid villi into dural venous sinuses

**Etiology**

- congenital versus acquired
- obstruction to CSF flow
- decreased CSF absorption
- increased CSF production (rarely) – e.g. choroid plexus papilloma (0.4-1% of intracranial tumours)

**Epidemiology**

- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1,000 live births

Clinical Features

- acute hydrocephalus
  - signs and symptoms of acute elevated ICP (see Elevated ICP, NS5)
  - impaired upward gaze ("sunset eyes") and/or CN VI palsy
- chronic/gradual onset hydrocephalus (i.e. NPH)
  - gradual onset of classic triad developing over weeks or months
    - pressure of ventricle on lower extremity motor fibres → gait disturbance (ataxia and apraxia usually initial symptoms)
    - pressure on cortical bowel/bladder centre → urinary incontinence
    - pressure on frontal lobes → dementia
  - CSF pressure can be measured within clinically “normal” range

Investigations

- CT/MRI (periventricular lucency suggests raised CSF pressure)
- ultrasound (through anterior fontanelle in infants)
- ICP monitoring (e.g. LP) may be used to investigate NPH, test response to shunting (lumbar tap test)
- radionuclide cisternography can test CSF flow and absorption rate (unreliable)
- β-2 transferrin assay to test for the presence of CSF leak

Treatment

- ventricular drainage
- surgical removal of obstruction (if possible) or excision of choroid plexus papilloma
- shunts
  - ventriculoperitoneal (VP): most common
  - ventriculopleural
  - ventriculo-atrial (VA): relatively increased risk of infections, shunt emboli
  - lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri
- third ventriculostomy (for obstructive hydrocephalus) via ventriculoscropy
- LPs for transient hydrocephalus (e.g. SAH), IVH in premature infants, etc.

## Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)

### Definition
- Raised intracranial pressure and papilledema without evidence of any mass lesion, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)

### Etiology
- Unknown (majority), but associated with
  - Lateral venous sinus thrombosis
  - Habitus/diet: obesity, hyper/hypovitaminosis A
  - Endocrine: reproductive age, menstrual irregularities, Addison’s/Cushing’s disease, thyroid irregularities
  - Hematological: iron deficiency anemia, polycythemia vera
  - Drugs: steroid administration or withdrawal, tetracycline, nalidixic acid, etc.
- Risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones (“fat, female, fertile, forties”)

### Epidemiology
- Incidence ~0.5/100,000 per year
- Usually in 3rd and 4th decade (F>M)

### Clinical Features
- Symptoms and signs of raised ICP (H/A in >90%, pulsatile intracranial noise), but no LOC or diplopia
- Decreased visual acuity, papilledema, visual field defect, optic atrophy (key morbidity)
- Usually self-limited, recurrence is common, chronic in some patients
- Risk of blindness is not reliably correlated to symptoms or clinical course
**Investigations**
- CT: normal
- CSF studies: normal
- MRI: must look for venous sinus thrombosis

**Treatment**
- rule out conditions that cause intracranial HTN (especially sinus thrombosis)
- discontinue offending medications, encourage weight loss, fluid/salt restriction
- pharmacotherapy: acetazolamide (decreases CSF production), thiazide diuretic, or furosemide
- if above fail: serial LPs, shunt
- optic nerve sheath decompression (if progressive impairment of visual acuity)
- 2 yr follow-up with imaging to rule out occult tumour, ophthalmology follow-up

---

### Tumours

#### Classification
- primary vs. metastatic, intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, but can be devastating due to expansion of mass in fixed volume of skull (mass effect)
- malignant: implies rapid growth, invasiveness, but rarely extracranial metastasis
- types of intracranial tumours (* = most common)
  - neuroepithelial tissue
    - astrocytic tumours: astrocytoma, glioblastoma
  - oligodendroglial tumours
  - oligoastrocytic tumours
  - neuronal and mixed neuronal-glial tumours: ganglion cell tumours, cerebral neurocytomas/neuroblastosomas
  - embryonal tumours: medulloblastoma, neuroectodermal
  - other: pineal, ependymal, and choroid plexus tumours
  - meningeal: meningiomas*, mesenchymal, hemangioblastomas
  - cranial and paraspinous nerves: schwannoma, neurofibroma
  - lymphomas and hematopoietic neoplasms
  - germ cell: germinomas, teratomas
  - pituitary adenomas
  - sellar region: craniopharyngiomas, spindle cell oncocytoma
  - cysts: epidermoid/dermoid cysts, colloid cysts
  - local extension: chordomas, glomus jugulare tumours
  - metastatic tumours

#### Clinical Features
- supratentorial lesions
  - progressive neurological deficit (70%)
  - frontal lobe: hemiparesis, dysphasia, personality changes, cognitive changes
  - temporal lobe: auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopsia

---

### DDx for Ring Enhancing Lesion on CT with Contrast

- Lesions (+ edema, necrosis, hemorrhage)
- Midline shifts and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)

---

**Primary Sources of Metastatic Brain Tumours**

- Lung: 44%
- Breast: 10%
- Kidney (RCC): 7%
- GI: 6%
- Melanoma: 3%

**Primary CNS lymphoma** reported in 5-20% of HIV infected patients

**Brain Metastasis**

- ~1/3 of all adult brain tumours
- Well circumscribed, often at grey-white matter junction
• symptoms suggestive of TIA (occlusion of vessel by tumour cells or 2nd "steal phenomenon" where blood is shunted from ischemic regions to non-ischemic regions and manifested as neurological changes)
• endocrine disturbances with pituitary tumours (e.g. Cushing’s disease, prolactinoma)
• rarely presents with hemorrhage

**Intracranial lesions**
- most commonly presents with signs of elevated ICP
  - headache
  - nausea and vomiting
  - papilledema
- diplopia (direct compression CN VI versus indirect compression from increased ICP)
- vertigo
- ataxia (due to cerebellar lesions)

**Familial syndromes associated with CNS Tumours**
- von Hippel-Lindau (hemangioblastoma of brain, spinal cord, and eye)
- tuberous sclerosis (giant cell astrocytoma, cortical tubers, and suppengydral nodules)
- neurofibromatosis type 1 and 2 (astrocytoma, bilateral acoustic neuroma respectively)
- Li-Fraumeni (astrocytoma)
- Turcot syndrome (glioblastoma multiforme)
- multiple endocrine neoplasia type 1 (MEN-1) (pituitary adenoma)

**Investigations**
- CT, MRI, stereotactic biopsy (tissue diagnosis), metastatic workup

**Treatment**
- conservative: serial Hx, Px, imaging for slow growing/benign lesions
- medical: corticosteroids to reduce cytotoxic cerebral edema, pharmacological (see *Pituitary Adenoma*, NS13)
- surgical: total or partial excision (decompressive, palliative), shunt if hydrocephaus
- radiotherapy: conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (e.g. Gamma Knife®)
- chemotherapy: e.g. alkylating agents (temozolomide)

**Investigations**
- CT, MRI, stereotactic biopsy (tissue diagnosis), metastatic workup

**Class I – Karnofsky performance status (KPS) ≥ 80**

Three prognostic groups based on 1,200 patients:
- Class I – Karnofsky performance status (KPS) > 80 yr with controlled primary (3 mo stability on imaging or newly diagnosed), no extracranial metastases (median survival 7.1 mo).
- Class II – everything else (median survival 4.2 mo).
- Class III – KPS < 70 (median survival 2.3 mo).

**Summary of Evidence for Single and Multiple Brain Metastases**
1) For patients with good performance status (e.g. KPS > 70), limited extracranial disease and resectable metastases, complete resection improves the probability of extended survival. WBRT in addition to resection improves local and overall brain control but does not affect overall survival or duration of functional independence.
2) For patients with a good prognosis (>3 mo expected survival), single brain metastases < 4 cm in size, good performance status, and controlled extracranial disease, the addition of radiosurgery to WBRT improves survival when compared with WBRT alone.
3) In patients with a good prognosis and up to 4 brain metastases < 4 cm in size, radiosurgery added to WBRT improves lesion site and overall brain control compared with WBRT alone, but does not influence survival. Therefore, WBRT alone may be considered in these patients.
4) The use of radiosurgery boost to WBRT may improve KPS and decrease the need for steroids at 6 mo in patients with up to 3 brain metastases.
5) For selected patients with poor life expectancy (< 3 mo), the use of WBRT may or may not significantly improve symptoms from brain metastases. Corticosteroids, or short course (20 Gy in 5 daily fractions) WBRT are reasonable options.
6) There is no evidence of a survival benefit with the combined use of radiosensitizers with WBRT.
7) Although chemotherapy trials have reported improved response rates with combined chemotherapy and WBRT, the addition of chemotherapy leads to increased toxicity and does not improve survival. The routine use of chemotherapy in the management of brain metastases is not generally recommended.

**Metastatic Tumours**
- most common brain tumour seen clinically
- 15-30% of cancer patients present with cerebral metastatic tumours
- most common sources: lungs, breast
- other sources: kidney, thyroid, stomach, prostate, testis, melanoma
- hematogenous spread most common

**Location**
- 80% are hemispheric, often at grey-white matter junction or junction of temporal-parietal-occipital lobes (likely emboli spreading to terminal MCA branches)

**Investigations**
- identify primary tumour
- metastatic workup (CXR, CT chest/abdo, abdominal U/S, bone scan, mammogram)
- CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
- MRI more sensitive, especially for posterior fossa
- consider biopsy in unusual cases, or if no primary identified
Treatment
• medical
  □ phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  □ dexamethasone to reduce edema given with ranitidine
  □ chemotherapy (e.g. small cell lung cancer)
• radiation
  □ stereotactic radiosurgery: for discrete, deep-seated/inoperable tumours
  □ multiple lesions: use WBRT; consider stereotactic radiosurgery if <3 lesions
  □ post-operative WBRT is commonly used
• surgical
  □ single/solitary lesions: use surgery and radiation

Prognosis
• median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo but varies depending on primary tumour type

Astrocytoma
• most common primary intra-axial brain tumour, common in 4th-6th decades

Table 7. Astrocytoma Grading System

<table>
<thead>
<tr>
<th>World Health Organization (WHO)</th>
<th>Typical CT/MRI Findings</th>
<th>Survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>I – Pilocytic astrocytoma</td>
<td>± mass effect, ± enhancement</td>
<td>&gt;10 yr, cure if gross total resection</td>
</tr>
<tr>
<td>II – Low grade/diffuse</td>
<td>Mass effect, no enhancement</td>
<td>5 yr</td>
</tr>
<tr>
<td>III – Anaplastic</td>
<td>Complex enhancement</td>
<td>1.5-2 yr</td>
</tr>
<tr>
<td>IV – Glioblastoma multiforme (GBM)</td>
<td>Necrosis (ring enhancement)</td>
<td>12 mo, 10% at 2 yr</td>
</tr>
</tbody>
</table>

Clinical Features
• sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
• symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

Investigations
• CT/MRI with contrast: variable appearance depending on grade
• hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
• low grade: most do not enhance and have calcification on CT
• high grade: most enhance with CT contrast dye/gadolinium

Treatment
• low grade diffuse astrocytoma
  □ close follow-up; radiation, chemotherapy, and surgery all valid options
  □ surgery: not curative, trend towards better outcomes
  □ radiotherapy alone or post-operative prolongs survival (retrospective evidence)
  □ chemotherapy; usually reserved for tumour progression
• high grade astrocytomas (anaplastic astrocytoma and GBM)
  □ surgery
    □ gross total resection: maximal safe resection + fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
    □ except: extensive dominant lobe GBM, significant bilateral involvement, end-of-life near, extensive brainstem involvement
    □ stereotactic biopsy if resection not possible, followed by fractionated radiation with 2 cm margin
  □ expectant (based on functional impairment – Karnofsky score <70; patient’s/family’s wishes)
  □ aim to prolong “quality” survival
  □ chemotherapy: ~20% response rate, temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene hypermethylation
• multiple gliomas: WBRT ± chemotherapy

Meningioma
• most common primary intracranial tumour, arise from arachnoid membrane
• often calcified, cause hyperostosis of adjacent bone
• classically see Psammoma bodies on histology
• common locations: parasagittal convexity or falx (70%), sphenoid wing, tuberculum sellae, foramen magnum, olfactory groove

WHO Classification of Meningioma (by histology)
Grade 1: low risk of recurrence
Grade 2: intermediate risk of recurrence
Grade 3: high risk of recurrence

Figure 10. High grade astrocytoma on CT

Bevacizumab Plus Radiotherapy-Temozolomide for Newly Diagnosed Glioblastoma

Purpose: To evaluate the effect of combined bevacizumab and radiotherapy-temozolomide in the treatment of newly diagnosed glioblastoma.

Study: Patients with supratentorial glioblastoma randomly assigned to receive intravenous bevacizumab or placebo plus radiotherapy and oral temozolomide for 30 wk total n cycles, followed by bevacizumab or placebo monotherapy. Outcomes were progression-free survival and overall survival.

Results: 458 patients in bevacizumab group, 463 patients in placebo. The median progression-free survival was longer in the bevacizumab group although there was a higher frequency of adverse events.

Conclusions: Early surgical resection of low grade gliomas is associated with better overall survival as compared to watchful waiting.
Clinical Features
- middle aged, slight female preponderance (M:F = 2:3), high progesterone receptors (increase in size with pregnancy), symptoms of increased ICP, focal deficits, usually solitary (10% multiple, likely with loss of NF2 gene/22q12 deletion)

Investigations
- CT with contrast: homogeneous, densely enhancing, along dural border ("dural tail"), well circumscribed
- contrast enhanced MRI provides better detail
- angiography
  - most are supplied by external carotid feeders (meningeal vessels)
  - also assesses venous sinus involvement, "tumour blush" commonly seen (prolonged contrast image)
- octreotide scintigraphy: to establish if expression of somatostatin receptor

Treatment
- conservative management for non-progressive, asymptomatic lesions
- surgery is treatment of choice if symptomatic or progression on sequential imaging (curative if complete resection)
- SRS may be an option for lesions <3 cm
- endovascular embolization to facilitate surgery
- SRS or XRT for recurrent atypical/malignant meningiomas

Prognosis
- >90% 5-yr survival, recurrence rate variable (often ~10-20%)
- depends on extent of resection (Simpson's classification)

Vestibular Schwannoma (Acoustic Neuroma)
- slow-growing (average of 1-10 mm/yr), benign posterior fossa tumour
- arises from vestibular component of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of neurofibromatosis type II
- epidemiology: all age groups affected, peaks at 4th-6th decades

Clinical Features
- compression of structures in CPA, often CN VIII (unilateral hearing loss 98%, tinnitus, disequilibrium), followed by CN V and VII
- ataxia and raised ICP are late features

Investigations
- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/specific), CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

Treatment
- conservative: serial imaging (CT/MRI q6mo) and audiometry
- radiation: stereotactic radiosurgery or fractionated radiotherapy
- surgery if: lesion >3 cm, brainstem compression, edema, hydrocephalus
  - curable if complete resection (almost always possible)
  - operative complications: CN VII, VIII dysfunction (only significant disability if bilateral), CSF leak

Pituitary Adenoma
- primarily from anterior pituitary, 3rd-4th decades, M=F
- incidence in autopsy studies approximately 20%
- classification
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
    - most common functional: prolactinomas, adrenocorticotropic, growth-hormone producing
  - differential: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm
Clinical Features
- mass effects
  - H/A
  - bitemporal hemianopsia (compression of optic chiasm)
  - CN III, IV, V1, V2, VI palsy (compression of cavernous sinus)
- endocrine effects
  - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
  - ACTH production: Cushing’s disease, hyperpigmentation
  - GH production: acromegaly/gigantism
  - panhypopituitarism (hypothyroidism, hypoadrenalism, hypogonadism)
  - associated MEN-1 syndrome
  - diabetes insipidus
- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
  - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, and panhypopituitarism
- CSF rhinorrhea and seizures (rare)
- signs and symptoms of subarachnoid hemorrhage (rare)

Investigations
- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolarity
- imaging (MRI with and without contrast)

Treatment
- medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing’s: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
- surgical
  - trans-sphenoidal, trans-ethmoidal, trans-cranial approaches for non-secreting adenomas causing mass effect and Cushing/acromegaly (50% cure rate)

Pus

Sources of Pus/Infection
- four routes of microbial access to CNS
  1. hematogenous spread (most common): arterial and retrograde venous
    - adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
    - children: congenital cyanotic heart disease with R to L shunt
    - immunosuppression (AIDS – toxoplasmosis)
  2. direct implantation (dural disruption)
    - trauma
    - iatrogenic (e.g. following LP, post-operative)
    - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site
    - (e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess)
  4. spread from PNS (e.g. viruses: rabies, herpes zoster)
- common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
  - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
  - treatment: surgical drainage and antibiotics, 20% mortality
- meningitis, encephalitis (see Infectious Diseases, ID18)
- cerebral abscess

Cerebral Abscess

Definition
- pus in brain substance, surrounded by tissue reaction (capsule formation)

Etiology
- modes of spread: 10-60% of patients have no cause identified
- pathogens
  - *Streptococcus* (most common), often anaerobic or microaerophilic
  - *Staphylococcus* (penetrating injury)
  - Gram-negatives, anaerobes (*Bacteroides, Fusobacterium*)
  - in neonates: *Proteus* and *Citrobacter* (exclusively)
- immunocompromised: fungi and protozoa (Toxoplasma, Nocardia, Candida albicans, Listeria monocytogenes, Mycobacterium, and Aspergillus)

Risk Factors
- lung abnormalities (infection, AV fistulas; especially Osler-Weber-Rendu syndrome [i.e. hereditary hemorrhagic telangiectasia])
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess

Clinical Features
- focal neurological signs and symptoms
  - H/A, decreased LOC; hemiparesis and seizures in 50%
  - mass effect, increased ICP and sequelae (cranial enlargement in children)
  - hemiparesis and seizures in 50%
  - ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

Complications
- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

Investigations
- CT scan often first test in emergency department
- MRI
  - imaging of choice
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
- WBC/ESR may be normal, blood cultures rarely helpful and LP contraindicated if large mass
- CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

Treatment
- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), C&S, fungal culture
- excision preferable if location suitable
- antibiotics
  - empirically: vancomycin + ceftriaxone + metronidazole or chloramphenicol or rifampin (6-8 wk therapy)
  - revise antibiotics when C&S known
- anti-convulsants (1-2 yr)
- follow-up CT is critical (do weekly initially, more frequent if condition deteriorates)

Prognosis
- mortality with appropriate therapy ~10%, permanent deficits in ~50%

---

</tbody>
</table>
Extradural ("Epidural") Hematoma

Etiology
- temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins

Epidemiology
- young adult, M>F = 4:1; rare before age 2 or after age 60
- 1-4% of traumatic head injuries

Clinical Features
- classic sequence (seen in <30%): post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
- signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, aphasia, seizures, HTN, and respiratory distress
- deterioration can take hours to days

Investigations
- CT without contrast: "lenticular-shaped" usually limited by suture lines but not limited by dural attachments

Treatment
- admission, close neurological observation with serial CT indicated if all of the following are present
  - small volume clot, minimal midline shift (MLS <5 mm), GCS >8, no focal deficit
  - otherwise, craniotomy to evacuate clot, follow up CT
  - mannitol pre-operative if elevated ICP or signs of brain herniation

Prognosis
- good with prompt management, as the brain is often not damaged
- worse prognosis if bilateral Babinski or decerebration pre-operative
- death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

Subdural Hematoma

ACUTE SUBDURAL HEMATOMA
- 1-2 d after bleeding onset

Etiology
- rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration

Risk Factors
- trauma, acceleration-deceleration injury, anticoagulants, alcohol, cerebral atrophy, infant head trauma

Clinical Features
- no lucid period, signs and symptoms can include altered LOC, pupillary irregularity, hemiparesis

Investigations
- CT: hyperdense concave "crescentic" mass, crossing suture lines

Treatment
- craniotomy if clinically symptomatic, if hematoma >1 cm thick, or if MLS >5 mm (optimal if surgery <4 h from onset); otherwise observe with serial imaging

Prognosis
- poor overall since the brain parenchyma is often injured (mortality range is 50-90%, due largely to underlying brain injury)
- prognostic factors: initial GCS and neurologic status, post-operative ICP

Use of Drains vs. No Drains After Burr-Hole Evacuation of Chronic Subdural Hematoma: A Randomized Control Trial

Purpose: To examine the effect of drains on recurrence rates of chronic subdural hematoma (SDH) and clinical outcomes.

Study: RCT with 269 patients ≥18 yr of age with chronic SDH. Half of the patients were randomly assigned to receive a subdural drain and the other half no drain after evacuation.

Results: Recurrence occurred in 9.3% of people with a drain and 24% without (p=0.003; 95% CI 0.14-0.70). Although rates of complications were the same between the study groups, mortality at 6 mo was 8.6% in the group receiving a drain and 18.1% in the group not receiving a drain (p=0.042; 95% CI 0.1-0.99).

Conclusions: Use of drains after burr-hole drainage of chronic SDH is safe and associated with a reduced recurrence and mortality at 6 mo.
CHRONIC SUBDURAL HEMATOMA
• ≥15 d after bleeding onset

Etiology
• many start out as acute SDH
• blood within the subdural space evokes an inflammatory response:
  ▪ fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot (forming a hygroma)
• course is determined by the balance of rebleeding from neomembranes and resorption of fluid

Risk Factors
• older, alcoholics, patients with CSF shunts, anticoagulants, coagulopathies

Clinical Features
• often due to minor injuries or no history of injury
• may present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ± seizures, progressive dementia, gait problem
• obtundation disproportionate to focal deficit; “the great imitator” of dementia, tumours

Investigations
• CT: hypodense (liquefied clot), crescentic mass

Treatment
• seizure prophylaxis only if post-traumatic seizure
• reverse coagulopathies
• burr hole drainage of liquefied clot indicated if symptomatic or thickness >1 cm; craniotomy if recurs more than twice

Prognosis
• good overall as brain usually undamaged, but may require repeat drainage

Cerebrovascular Disease

Ischemic Cerebral Infarction (80%)
• embolic, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc. (see Neurology, N50)

Intracranial Hemorrhage (20%)
• SAH, spontaneous ICH, IVH

Figure 15. Subdural hematoma on CT

Figure 16. Aneurysms of the Circle of Willis

Types of Aneurysms
Saccular  Fusiform  Dissecting

1. Anterior communicating artery, 30%
2. Middle cerebral artery, 20%
3. Internal carotid/posterior communicating artery, 30%
4. Basilar tip, 7%
5. Superior cerebellar artery, 3%
6. Vertebobasilar junction, 2%
7. Posterior inferior cerebellar artery, 3%

Hemicraniectomy in Older Patients with Extensive Middle-Cerebral-Artery Stroke
NEJM 2014;370:1091-1100

Purpose: To determine if early decompressive hemicraniectomy reduces mortality among patients >60 yr.

Study: 112 patients >60 yr (median age 70 yr) with malignant MCA infarction randomly assigned to conservative ICU treatment versus hemicraniectomy. Endpoint was survival without severe disability (modified Rankin scale score 0-4).

Results: The proportion of patients who survived without severe disability was 38% in the hemicraniectomy group and 18% in the control group (OR 2.91, 95% CI 1.06-7.49). Modified Rankin scale scores in hemicraniectomy versus control group in terms of percentages of patients:
  - 0-2 (0%, 0%), 3 or moderate disability (7%, 3%), 4 or moderate severe disability (32%, 19%), 5 or severe disability (23%, 13%) and 6 or death (33%, 70%). Infections were more frequent in the hemicraniectomy group and herniation more frequent in the control group.

Conclusions: Hemicraniectomy increased survival without severe disability among patients >60 yr with a malignant MCA infarction.
Subarachnoid Hemorrhage

Definition
- bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

Etiology
- trauma (most common)
- spontaneous
  - ruptured aneurysms (75-80%)
  - idiopathic (14-22%)
  - AVMs (4-5%)
- coagulopathies (iatrogenic or primary), vasculitides, tumours, cerebral artery dissections (<5%)

Epidemiology
- ~10-28/100,000 population/yr
- peak age 55-60, 20% of cases occur under age 45

Risk Factors
- HTN
- pregnancy/parturition in patients with pre-existing AVMs, eclampsia
- oral contraceptive pill
- substance abuse (cigarette smoking, cocaine, alcohol)
- conditions associated with high incidence of aneurysms (see Intracranial Aneurysms, NS21)

Clinical Features of Spontaneous SAH
- sudden onset (seconds) of severe "thunderclap" H/A usually following exertion and described as the "worst headache of my life" (up to 97% sensitive, 12-25% specific)
- N/V, photophobia
- meningismus (neck pain/stiffness, positive Kernig's and Brudzinski's sign)
- decreased LOC (due to either raised ICP, ischemia, seizure)
- focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
- ocular hemorrhage in 20-40% (due to sudden raised ICP compressing central retinal vein)
- reactive HTN
- sentinel bleeds
  - represents undiagnosed SAH
  - SAH-like symptoms lasting <1 d ("thunderclap H/A")
  - may have blood on CT or LP
  - ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
- differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

Investigations
- non-contrast CT - for diagnosis of SAH
  - 98% sensitive within 12 h, 93% within 24 h; 100% specificity
  - may be negative if small bleed or presentation delayed several days
  - acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
- lumbar puncture (highly sensitive) - for diagnosis of SAH if CT negative but high suspicion:
  - elevated opening pressure (>18 cmH2O)
  - bloody initially, xanthochromic supernatant with centrifugation ("yellow") by ~12 h, lasts 2 wk
  - RBC count usually >100,000/mm³ without significant drop from first to last tube (in contrast to traumatic tap)
  - elevated protein due to blood breakdown products
- four vessel cerebral angiography ("gold standard" for aneurysms)
  - demonstrates source of SAH in 80-85% of cases
  - angiogram negative SAH: repeat angiogram in 7-14 d, if negative \( \Rightarrow \) "perimesencephalic SAH"
- MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

"Triple H" Therapy for Vasospasm

HTN
Hypervolemia
Hemodilution

Calcium Antagonists for Aneurysmal Subarachnoid Hemorrhage

Introduction: This study looked to review the evidence in regards to whether calcium antagonists improve the outcome in patients with aneurysmal subarachnoid hemorrhage.

Methods/Population: The review included 3,361 patients presenting with aneurysmal subarachnoid hemorrhage from 16 RCTs comparing treatment with calcium antagonists vs. control from 1980 to March 2006.

Results: The results were based mainly on one large trial of oral nimodipine, which showed a RR of 0.67 (95% CI 0.55-0.81) and the evidence for other calcium agents was not statistically significant.

Conclusion: The authors endorse the use of oral nimodipine in patients with aneurysmal subarachnoid hemorrhage.

Complications

- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood – can lead to delayed cerebral ischemia and death
  - onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
  - clinical features (new onset ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor e.g. pronator drift)
  - risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
  - "symptomatic" vasospasm in 20-30% of SAH patients
  - "radiographic" vasospasm in 30-70% of arteriograms performed 7 d following SAH
  - diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
  - risk of cerebral infarct and death
  - treatment
    - hyperdynamic ("triple H") therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
    - direct vasodilation via angioplasty or intra-arterial verapamil for refractory cases
    - hydrocephalus (15-20%): due to blood obstructing arachnoid granules
    - can be acute or chronic, requires extraventricular drain (EVD) or shunt, respectively
    - neurogenic pulmonary edema

Treatment

- admit to ICU or NICU
  - oxygen/ventilation prn
  - NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
  - aim to maintain sBP = 120-150 (balance of vasospasm prophylaxis, risk of re-bleed, risk of hypotension since CBF autoregulation impaired by SAH)
  - cardiac rhythm monitor, Foley prn, strict monitoring of ins and outs
- medications
  - IV NS with 20 mmol KCl/L at 125-150 cc/h
  - nimodipine 60 mg PO/NG q4h x 21 d for delayed cerebral ischemia neuroprotection; may discontinue earlier if patient is clinically well
  - seizure prophylaxis: levetiracetam (Keppra®) 500 mg PO/IV q12h x 1 wk
  - mild sedation prn

Background: Two rules for SAH diagnosis exist. A clinical prediction rule states that patients with acute severe H/A but without the clinical variables age ≥40 yr, neck pain, loss of consciousness, or onset of H/A with exertion are at low risk for SAH. An imaging prediction rule bases diagnosis on non-contrast cranial CT for patients within 6 h of H/A onset.

Methods: Matched case-control study of 55 patients at 21 emergency departments between 2000 and 2011, and diagnoses were verified by lumbar puncture.

Results: The clinical prediction rule for diagnosis of SAH was 97.1% sensitive, 22.7% specific, and had a negative likelihood ratio of 0.13. Using the imaging prediction rule resulted in a false negative rate of 20%.

Conclusions: Performing the clinical and imaging rules together has the potential for maximizing sensitivity of prediction and reducing rates of lumbar puncture, but using imaging alone can result in missed cases.
hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECFV loss), not SIADH
• diabetes insipidus
• cardiac: arrhythmia (>50% have ECG changes), MI, CHF

Prognosis
• 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
• 30% of survivors have moderate to severe disability
• a major cause of mortality is rebleeding, for untreated aneurysms:
  ▪ risk of rebleed: 4% on first day, 15-20% within 2 wk, 50% by 6 mo
  ▪ if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
  ▪ only prevention is early clipping or coiling of “cold” aneurysm
  ▪ rebleed risk for “perimesencephalic SAH” is approximately same as for general population

Intracerebral Hemorrhage

Definition
• hemorrhage within brain parenchyma, accounts for ~10% of strokes
• can dissect into ventricular system (IVH) or through cortical surface (SAH)

Etiology
• HTN (usually causes bleeds at putamen, thalamus, pons, and cerebellum)
• hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
• vascular anomalies
  ▪ aneurysm, AVMs, and other vascular malformations (see Vascular Malformations, NS22)
  ▪ venous sinus thrombosis
  ▪ arteriopties (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
• tumours (1%): often malignant (e.g. GBM, lymphoma, metastases)
• drugs (amphetamine, cocaine, alcohol, anticoagulants, etc.)
• coagulopathy (iatrogenic, leukemia, TTP, aplastic anemia)
• CNS infections (fungal, granulomas, herpes simplex encephalitis)
• post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contrecoup mechanism)
• eclampsia
• post-operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
• idiopathic

Epidemiology
• 12-15 cases/100,000 population/yr

Risk Factors
• increasing age (mainly >55 yr)
• male gender
• HTN
• Black/Asian > Caucasian
• previous CVA of any type (23x risk)
• both acute and chronic heavy alcohol use; cocaine, amphetamines
• liver disease
• anticoagulants

Clinical Features
• TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
• gradual onset of symptoms over minutes-hours, usually during activity
• H/A, N/V, and decreased LOC are common
• specific symptoms/deficits depend on location of ICH

Investigations
• hyperdense blood on non-contrast CT
• CTA routine, if spot sign demonstrated there is high likelihood of clot growth

Treatment
• medical
  ▪ decrease MAP to pre-morbid level or by ~20% (target BP 140/90)
  ▪ check PTT/INR, and correct coagulopathy
  ▪ control raised ICP (see Intracranial Pressure Dynamics, NS4)
  ▪ levetiracetam/phenytoin for seizure prophylaxis
  ▪ follow electrolytes (SIADH common)
  ▪ angiogram to rule out vascular lesion unless >45 yr, known HTN, and putamen/thalamic/ posterior fossa ICH (yield ~0%)
surgical
- craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumour, cavernoma), ventriculostomy to treat hydrocephalus
- indications
  - symptoms of raised ICP or mass effect
  - rapid deterioration (especially if signs of brainstem compression)
  - favourable location (e.g. cerebellar, non-dominant hemisphere)
  - young patient (<50 yr)
  - if tumour, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
- contraindications
  - small bleed: minimal symptoms, GCS >10
  - poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
  - medical reasons (e.g. very elderly, severe coagulopathy, difficult location [e.g. basal ganglia, thalamus])

Prognosis
- 30-d mortality rate 44%, mostly due to cerebral herniation
- rebleed rate 2-6%, higher if HTN poorly controlled

### Intracranial Aneurysms

#### Epidemiology
- prevalence 1-4% (20% have multiple)
- F>M; age 35-65 yr

#### Risk Factors
- autosomal dominant polycystic kidney disease (15%)
- fibromuscular dysplasia (7-21%)
- AVMs
- connective tissue diseases (Ehlers-Danlos, Marfan)
- family history
- bacterial endocarditis
- Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
- atherosclerosis and HTN
- trauma

#### Types
- saccular (berry)
  - most common type
  - located at branch points of major cerebral arteries (Circle of Willis)
- 85-95% in carotid (anterior) system, 5-15% in vertebrobasilar (posterior) circulation
- fusiform
  - atherosclerotic
  - more common in vertebrobasilar system, rarely rupture
- infectious
  - secondary to any infection of vessel wall, 20% multiple
- 60% Streptococcus and Staphylococcus
- 3-15% of patients with bacterial endocarditis

**AC** = anterior cerebral/anterior communicating artery; **IC** = internal carotid artery; **MC** = middle cerebral artery; **PC** = posterior cerebral artery; **PCComm** = posterior communicating artery

**Clinical Presentation**
- rupture (90%), most often SAH, 20% ICH, 3% subdural bleed
- sentinel hemorrhage (‘thunderclap H/A’) → requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
  - internal carotid or anterior communicating aneurysm may compress:
    - the pituitary stalk or hypothalamus causing hypopituitarism
    - the optic nerve or chiasm producing a visual field defect
  - basilary artery aneurysm may compress midbrain, pons (limb weakness), or CN III
  - posterior communicating artery aneurysm may produce CN III palsy
  - intracavernous aneurysms (CN III, IV, V1, V2, VI)

---

**Risk of Recurrent Subarachnoid Hemorrhage, Death, or Dependence and Standardized Mortality Ratios after Clipping or Coiling of an Intracranial Aneurysm in the International Subarachnoid Aneurysm Trial (ISAT): Long-Term Follow-Up**

**Objective:** To assess the long-term risk of death, disability, and rebleeding in patients randomly assigned to clipping or endovascular coiling after rupture of an intracranial aneurysm in the follow-up of the ISAT trial.

**Methods:** Randomized controlled trial comparing endovascular coiling treatment with craniotomy and clipping for ruptured intracranial aneurysms in 2,143 patients who were considered eligible for either modality of therapy. Annual follow-up was done for a mean length of 9 yr to assess long-term survival and dependency.

**Results:** 10 patients in the coiled group and 3 patients in the clipped group had rebleed from the original aneurysm. In patients with ruptured intracranial aneurysm, survival the survival rate at 5 yr after endovascular coiling was higher at 89% vs. 85% for neurosurgical clipping (relative risk 0.77, p=0.03). The likelihood of independence at 5 yr following treatment is the same for both groups (83% for clipping vs. 82% for clipping).

**Conclusion:** The risk of death at 5 yr was significantly lower in the clipped group than it was in the coiled group. There was a small increased risk of recurrent bleeding from a coiled aneurysm compared with a clipped aneurysm.

---

**Long-Term, Serial Screening for Intracranial Aneurysms in Individuals with a Family History of Aneurysmal Subarachnoid Hemorrhage: A Cohort Study**

**Purpose:** To examine the yield of long-term serial screening for intracranial aneurysms for individuals with a positive family history of aneurysmal subarachnoid hemorrhage (aSAH) (two or more first-degree relatives who have had aSAH or unruptured intracranial aneurysms).

**Study:** Screening results from April 1 1993 to April 1 2013 were reviewed in a cohort study. MRA or CTA was done from age 16-18 to 65-70 yr. After a negative screen, individuals were advised to contact the clinic in 5 yr for follow up.

**Results:** Aneurysms were identified in 11% of individuals at first screening (n=450), 8% at second screening (n=281), 5% at third screening (n=128), and 5% at fourth screening (n=63). Smoking (OR 2.7, 95% CI 1.2-5.9), history of previous aneurysms (3.8, 95% CI 1.2-12.3), and familial history of aneurysms (3.5, 1.8-6.1) were significant risk factors for aneurysms at first screening. History of previous aneurysms was the only significant risk factor for aneurysms at follow-up screening (HR 4.5, 95% CI 1.1-18.7).

**Conclusion:** The benefit of long-term screening in individuals with a family history of aSAH is substantial up to and after 10 yr of follow-up and two initial negative screens.
- distal embolization (e.g. amaurosis fugax)
- seizures
- I/H/A (without hemorrhage)
- incidental CT or angiography finding (asymptomatic)

Investigations
- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

Treatment
- ruptured aneurysms
  - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
  - treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling) or flow diversion stents, wrapping (last resort)
  - choice of surgery vs. coiling not yet well defined, consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition. In general:
    - coiling: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    - clipping: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
- unruptured aneurysms
  - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
  - no clear evidence on when to operate: need to weigh life expectancy
  - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
  - generally treat unruptured aneurysms >10 mm
  - consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
  - follow smaller aneurysms with serial angiography

Vascular Malformations

Types
- arteriovenous malformations (AVMs)
- cavernous malformations (cavernomas, cavernous hemangiomas/angiomas)
- venous angio\textit{m}a
- capillary telangiectasias
- arteriovenous fistula (AVF) (carotid-cavernous fistula, dural AVF, vein of Galen aneurysm)
- "angiographically occult vascular malformations" (any type, 10% of malformations)

Arteriovenous Malformations

Definition
- tangle of abnormal vessels/arteriovenous shunts, with no intervening capillary beds or brain parenchyma; usually congenital

Epidemiology
- prevalence ~0.14%, M:F = 2:1, average age at diagnosis = 33 yr
- 15-20% of patients with hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) will have cerebral AVMs

Clinical Features
- hemorrhage (40-60%): small AVMs are more likely to bleed due to direct high pressure AV connections
- seizures (50%): more common with larger AVMs
- mass effect
- focal neurological signs secondary to ischemia (high flow → "steal phenomena")
- localized headache, increased ICP
- bruit (especially with dural AVMs)
- may be asymptomatic ("silent")

Investigations
- MRI (flow void), MRA
- angiography (7%) will have one or more associated aneurysms

Treatment
- decreases risk of future hemorrhage and seizure
  - surgical excision is treatment of choice
  - SRS (stereotactic radiosurgery) is preferred for small (<3 cm) or very deep lesions
  - endovascular embolization (glue, balloon) can be curative (5%) or used as adjuvant to surgery or SRS in larger lesions
  - conservative (e.g. palliative embolization, seizure control if necessary)

Spetzler-Martin AVM Grading Scale

- "Untreated Clinical Course of Cerebral Cavernous Malformations: A Prospective, Population-Based Cohort Study" by [3]

[1]: Lancet Neurol 2012;11:217-224
Prognosis
• 10% mortality, 30-50% morbidity (serious neurological deficit) per bleed
• risk of major bleed in untreated AVMs: 2-4% per year

Cavernous Malformations
• benign vascular hamartoma consisting of irregular sinusoidal vascular channels located within the brain without intervening neural tissue or associated large arteries/veins
• several genes now described: CCM1, CCM2, CCM3
• prevalence of 0.1-0.2%, both sporadic and hereditary forms described

Clinical Features
• seizures (60%), progressive neurological deficit (50%), hemorrhage (20%), H/A
• often an incidental finding
• hemorrhage risk less than AVM, usually minor bleeds

Investigations
• T2WI MRI (non-enhancing) gradient echo sequencing (best for diagnosis)

Treatment
• surgical excision
  • only appropriate for symptomatic lesions that are surgically accessible (supratentorial lesions are less likely to bleed than infratentorial lesions)

EXTRACRANIAL PATHOLOGY

Approach to Limb/Back Pain

Stereotactic Radiosurgery for Cavernous Malformations
J Neurosurg 2000;93:987-989

Introduction: The use of radiosurgery for treatment of cerebral cavernous malformations (CM) is controversial. The safety and efficacy of CM radiosurgery is described.

Methods: Retrospective review of 17 patients with CM who underwent radiosurgery over a 10 yr period. All patients had at least 2 documented hemorrhages prior to therapy.

Results: Annual hemorrhage rate 51 mo preceding surgery was 40.1% compared to 8.8% in first 2 yr after radiosurgery and 2.9% thereafter. However, 41% of patients developed a permanent radiation-related morbidity.

Conclusions: Improbable to conclude that radiosurgery protects patients with CMs against future hemorrhage.
Root Compression

Differential Diagnosis
- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

Cervical Disc Syndrome

Etiology
- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)

Clinical Features
- pain in arm follows nerve root distribution, worse with neck extension, ipsilateral rotation, and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

Investigations
- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG, nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue

Treatment
- conservative
  - no bedrest unless severe radicular symptoms
  - activity modification, patient education (reduce sitting, lifting)
  - physiotherapy, exercise programs focus on strengthening core muscles
  - analgesics, NSAIDs are more efficacious
  - avoid cervical manipulation, like traction
- surgical indications
  - anterior cervical disectomy is usual approach
  - intractable pain despite adequate conservative treatment for >3 mo
  - progressive neurological deficit

Prognosis
- 95% improve spontaneously in 4-8 wk

Cervical Spondylosis

Definition
- progressive degenerative process of cervical spine leading to canal stenosis – congenital spinal stenosis, degeneration of intervertebral discs, hypertrophy of lamina, dura, or ligaments, subluxation, altered mobility, telescoping of the spine due to loss of height of vertebral bodies, alteration of normal lordotic curvature
- resultant syndromes include mechanical neck pain, radiculopathy (root compression), myelopathy (spinal cord compression) and combinations

Epidemiology
- typically begins at age 40-50, M>F, most commonly at the C5-C6 > C6-C7 levels

Pathogenesis
- any of: disc degeneration/herniation, osteophyte formation, ossification, and hypertrophy of ligaments
- pathophysiology includes static compression, dynamic compression, and vascular compromise
Clinical Features
- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling’s test)
- the earliest symptoms are gait disturbance and lower extremity weakness or stiffness
- occipital H/A is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder and arm pain, paresthesias and numbness
- cervical myelopathy may be characterized by weakness (upper > lower extremity), decreased dexterity, and sensory changes
- UMN findings such as hyperreflexia, clonus, and Babinski reflex may be present
- most worrisome complaint is lower extremity weakness (corticospinal tracts)
- myelopathy may be associated with funicular pain, characterized by burning and stinging ± Lhermitte’s sign (lightning-like sensation down the back with neck flexion)

Investigations
- x-ray of cervical spine ± flexion/extension (alignment, fractures)
- MRI most useful for determination of compression of the neural element
- CT is only used for better determination of bony anatomy (i.e. OPLL)
- EMG/nerve conduction studies reserved for peripheral nerve investigation

Treatment
- nonsurgical: prolonged immobilization with cervical bracing (limit movement to minimize cumulative trauma to spinal cord), bed rest, anti-inflammatory medications
- surgical: anterior approach (anterior cervical disectomy or corpectomy), posterior approach (decompressive cervical laminectomy)
- surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain
- complete remission almost never occurs. Surgical decompression may stop progression of disease

Etiology
- postilaterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
- far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
- central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

Clinical Features
- initially back pain, then leg pain > back pain
- limited back movement (especially forward flexion) due to pain
- motor weakness, dermatomal sensory changes, decreased reflexes
- exacerbation with valsalva; relief with flexing the knee or thigh
- nerve root tension signs
  - straight leg raise (SLR, Lasegue’s test) or crossed SLR (pain should occur at less than 60º) suggests L5, S1 root involvement
  - femoral stretch test suggests L2, L3, or L4 root involvement

Investigations
- MRI is modality of choice
- x-ray spine (only to rule out other lesions), CT (bony anatomy)
- myelogram and post-myelogram CT (only if MRI is contraindicated)

Treatment
- conservative (same as cervical disc disease)
- surgical indications
  - same as cervical disc + cauda equina syndrome

Prognosis
- 95% improve spontaneously within 4-8 wk
- do not follow patients with serial MRIs; clinical status is more important at guiding management

</tbody>
</table>

Cauda Equina Syndrome

**Etiology**
- compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
- decreased space in the vertebral canal below L2
- common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumour

**Clinical Features**
- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
  - weakness/paraparesis in multiple root distribution
  - reduced deep tendon reflexes (knee or ankle)
- autonomic
  - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
- sensory
  - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
  - bilateral sensory loss or pain: depends on the level affected
  - saddle area (S2-S5) anesthesia
  - sexual dysfunction (late finding)

**Investigations**
- urgent MRI to confirm compression of S2-S3-S4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present; volumes controversial but anything over 250 cc in a healthy individual is cause for concerns

**Treatment**
- surgical decompression (<48 h) to preserve bowel, bladder, and sexual function, and/or to prevent progression to paraplegia

**Prognosis**
- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

Lumbar Spinal Stenosis

**Etiology**
- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

**Clinical Features**
- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

**Investigations**
- MRI is the optimal investigation to confirm and localize the level of stenosis (unlike nerve root compression which can be localized with clinical exam)

**Treatment**
- conservative: NSAIDs, analgesia
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in de-stabilization)
Neurogenic Claudication

Etiology
- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

Clinical Features
- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- induced by variable degrees of exercise or standing
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

Investigations
- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

Treatment
- same as for lumbar spinal stenosis

Intradural Intramedullary Lesions

Syringomyelia (Syrinx)

Definition
- cystic cavitation of the spinal cord
- presentation is highly variable, usually progresses over months to years
- initially pain, weakness; later atrophy and loss of pain and temperature sensation

Etiology
- 70% are associated with Chiari I malformation, 10% with basilar invagination
- post-traumatic
- tumour
- tethered cord

Clinical Features
- nonspecific features for any intramedullary spinal cord pathology:
  - initially pain, weakness, atrophy, loss of pain and temperature in upper extremities (central syrinx) with progressive myelopathy over years
  - sensory loss with preserved touch and proprioception in a band-like distribution at the level of cervical syrinx
  - sensory loss with preserved touch and proprioception in a band-like distribution at the level of cervical syrinx
  - dysesthetic pain often occurs in the distribution of the sensory loss
  - LMN arm/hand weakness or wasting
  - painless neuropathic arthropathies (Charcot's joints), especially in the shoulder and neck due to loss of pain and temperature sensation

Investigations
- MRI is best method, myelogram with delayed CT

Treatment
- treat underlying cause (e.g. posterior fossa decompression for Chiari I, surgical removal of tumour if causing a syrinx)
- rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

Spinal Cord Syndromes

- spinal cord injury impairment classified according to ASIA score
- ASIA A: complete, no motor/sensory below neurological level including S4/5
- ASIA B: incomplete, sensory but not motor function preserved below neurological level including S4/5
• ASIA C: incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade <3
• ASIA D: incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade 3 or more
• ASIA E: normal motor and sensory function

Complete Spinal Cord Lesion
• bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
• about 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

Incomplete Spinal Cord Lesion
• any residual function at ≥4 segments below lesion
• signs include sensory/motor function in lower limbs and “sacral sparing” (perianal sensation, voluntary rectal sphincter contration)

Table 13. Comparison Between Incomplete Spinal Cord Lesion Syndromes

Peripheral Nerves

• see Neurology, N34

Seddon’s Classification of Peripheral Nerve Injury
• class I: neurapraxia – axon structurally intact but fails to function; recovery within hours to months (average 6-8 wk)
• class II: axonotmesis – axon and myelin sheath disrupted but endoneurium and supporting structures intact → Wallerian degeneration of axon segment distal to injury → spontaneous axonal recovery at 1 mm/d, max at 1-2 yr
• class III: neurotmesis – nerve completely transected, need surgical repair for possibility of recovery
• etiologies: ischemia, nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve

Investigations
• neurological exam (power, sensation, reflexes), localization via Tinel’s sign (paresthesias elicited by tapping along the course of a nerve)
• electrophysiological studies (EMG, nerve conduction study) may be helpful in assessing nerve integrity and monitoring recovery, not helpful until 2-3 wk post-injury
• labs: blood work, CSF
• imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography
• angiogram if vascular damage is suspected

Treatment
• early neurosurgical consultation if injury is suspected
• entrapment
  † conservative: prevent repeated stress/injury, physiotherapy, NSAIDs, local anesthesia/steroid injection
  † surgical: nerve decompression ± transposition for progressive deficits, muscle weakness/atrophy, failure of medical management
• stretch/contusion
  † follow-up clinically for recovery; exploration if no recovery in 3 mo
• axonotmesis
  † if no evidence of recovery, resect damaged segment
  † prompt physical therapy and rehabilitation to increase muscle function, maintain joint range
  of motion, and maximize return of useful function
  † recovery usually incomplete
• neurotmesis
  † surgical repair of nerve sheath unless known to be intact (suture nerve sheaths directly if
  ends approximate or nerve graft [usually sural nerve])
  † clean laceration: early exploration and repair
  † contamination or associated injuries: tag initially with nonabsorbable suture, reapproach
  within 10 d

Complications
• neuropathic pain: with neuroma formation
• complex regional pain syndrome: with sympathetic nervous system involvement

SPECIALTY TOPICS

Neurotrauma

Trauma Management (see Emergency Medicine, ER7)

Indications for Intubation in Trauma
1. depressed LOC (patient cannot protect airway): usually GCS ≤ 8
2. need for hyperventilation
3. severe maxillofacial trauma: patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management
   † if basal skull fracture suspected, avoid nasotracheal intubation as may inadvertently enter
   brain
   † note: intubation prevents patient's ability to verbalize for determining GCS

Trauma Assessment

INITIAL MANAGEMENT

ABCs of Trauma Management
• see Emergency Medicine, ER7

NEUROLOGICAL ASSESSMENT

Mini-History
• period of LOC, post-traumatic amnesia, loss of sensation/function, type of injury/accident

Neurological Exam
• GCS
• head and neck (lacerations, bruises, basal skull fracture signs, facial fractures, foreign bodies)
• spine (palpable deformity, midline pain/tenderness)
• eyes (pupillary size and reactivity)
• brainstem (breathing pattern, CN palsies)
• cranial nerve exam
• motor exam, sensory exam (only if GCS is 15), reflexes
• sphincter tone
• record and repeat neurological exam at regular intervals

Investigations
• spinal injury precautions (cervical collar) are continued until C-spine is cleared
• CT/L-spine x-rays
  † AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer's view if necessary) or CT
  † rarely done: oblique views looking for pars interarticularis fracture ("Scottie dog" sign)
• CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss
  of mastoid or sinus air spaces, blood in cisterns, pneumocephalus
• cross and type, ABG, CBC, drug screen (especially alcohol)
• chest and pelvic x-ray as indicated

TREATMENT

Treatment for Minor Head Injury
• observation over 24-48 h
• wake every hour
• judicious use of sedatives or pain killers during monitoring period

Glasgow Coma Scale

</table>

Best response for each component recorded individually (e.g. E3V3M5)

≥ 13 is mild injury; 9-12 is moderate injury; ≤ 8 is severe injury

Assessment of Spine CT/X-Ray (Parasagittal View)

ABCDs
Alignment (columns: anterior vertebral line, posterior vertebral line, spinolaminar line, posterior spinous line)
Bone (vertebral bodies, facets, spinous processes)
Cartilage
Disc (disc space and interspinous space)
Soft tissues

• Never do lumbar puncture in head injury unless increased ICP has been ruled out
• All patients with head injury have C-spine injury until proven otherwise
• Suspect hematoma in alcoholic-related injuries
• Low BP after head injury means injury elsewhere
• Must clear spine both radiologically AND clinically
Treatment for Severe Head Injury (GCS ≤8)
- clear airway and ensure breathing (if GCS ≤8, intubate)
- secure C-spine
- maintain adequate BP
- monitor for clinical deterioration
- monitor and manage increased ICP if present (see Herniation Syndromes, NS6)

Admission required if:
- skull fracture (indirect signs of basal skull fracture, see Head Injury)
- confusion, impaired consciousness, concussion with >5 min amnesia
- focal neurological signs, extreme H/A, vomiting, seizures
- unstable spine
- use of alcohol
- poor social support

Head Injury

Epidemiology
- M:F = 2-3:1

Pathogenesis
- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/ mesencephalic hemotympanum
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
  - low velocity: highest damage to structures on entry/exit path
  - high velocity: highest damage away from missile tract

Skull Fractures
- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
  - internal fractures into sinus may lead to meningitis, pneumocephalus
  - risk of operative bleed may limit treatment to antibiotics
- basal skull fractures: not readily seen on x-ray; rely on clinical signs
  - retroauricular ecchymoses (Battle’s sign)
  - peri-orbital ecchymoses (raccoon eyes)
  - hemotympanum
- CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

Cranial Nerve Injury
- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
  - CN II: local eye/orbit injury
  - CN III, IV, VI: if herniation secondary to mass
  - CN VIII: repair of ossicles
- CN injuries that improve
  - CN I: recovery may occur in a few months; most do not improve
  - CN III, IV, VI: majority recover
  - CN VII: recovery with delayed lesions
  - CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

Arterial Injury
- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

Intracranial Bleeding
- see Blood, NS15 and Cerebrovascular Disease, NS17
Brain Injury

Primary Impact Injury
- mechanism of injury determines pathology: penetrating injuries, direct impact
  - low velocity: local damage
  - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
  - American Academy of Neurology (AAN) Classification
  - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow)
  - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
  - high density areas on CT ± mass effect
  - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
  - wide variety of damage results
  - may tear blood vessels (hemorrhagic foci)
  - often the cause of decreased LOC if no space-occupying lesion on CT

Secondary Pathologic Processes
- same subsequent biochemical pathways for each traumatic etiology
- delayed and progressive injury to the brain due to
  - high glutamate release → NMDA receptor activation → cytotoxic cascade
  - cerebral edema
  - intracranial hemorrhages
  - ischemia/infarction
  - raised ICP, intracranial HTN
  - hydrocephalus

Extracranial Conditions
- hypoxemia
  - due to trauma to the chest, upper airway, brainstem
  - extremely damaging to vulnerable brain cells
  - leads to ischemia, raised ICP
- hypercarbia
  - leads to raised ICP (secondary to vasodilation)
- systemic hypotension
  - caused by blood loss (e.g. ruptured spleen)
  - loss of cerebral autoregulation leads to decreased CPP, ischemia
- hyperpyrexia
  - leads to increased brain metabolic demands → ischemia
- fluid and electrolyte imbalance
  - iatrogenic (most common)
  - SIADH caused by head injury
  - diabetes insipidus (DI)
  - may lead to cerebral edema and raised ICP
  - coagulopathy

Intracranial Conditions
- raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

Brain Injury Outcomes
  - nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
- moderately traumatic (GCS 9–12): proportional to age (>40) and CT findings; 60% good recovery, 26% moderately disabled, 7% severely disabled, 7% vegetative/dead
- severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

Late Complications of Head/Brain Injury
- seizures: 5% of head injury patients develop seizures
  - incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
- post-traumatic seizure may be immediate, early, or late
- presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
- meningitis: associated with CSF leak from nose or ear
- hydrocephalus: acute hydrocephalus or delayed normal pressure hydrocephalus (NPH)
Spinal Cord Injury

• see Orthopedics, OR23 and Emergency Medicine, ER9

Neurogenic and Spinal Shock
1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by:
   • interruption of sympathetics (unopposed parasympathetics) below the level of injury
   • loss of muscle tone due to skeletal muscle paralysis below level of injury → venous pooling
   • blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the spinal cord injury, causing flaccid paralysis and areflexia for variable periods

Whiplash-Associated Disorders
• definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck

Initial Management of SCI
• major causes of death in SCI are aspiration and shock
• the following patients should be treated as having a SCI until proven otherwise:
  • all victims of significant trauma
  • minor trauma patients with decreased LOC or complaints of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

Stabilization and Initial Evaluation in the Hospital
1. ABCs, immobilization (backboard/head strap), oxygenation, Foley catheter to urometer, temperature regulation
2. hypotension: maintain sBP >90 mmHg with pressors (dopamine), hydration, and atropine
   • DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see Trauma Assessment, NS29)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
   • 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
   • flexion-extension views to disclose occult instability
   • CT scan (bony injuries) typically most trauma centers use CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners
   • MRI mandatory if neurologic deficits (soft tissue injuries)

Medical Management Specific to SCI
• option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
• ± decompression in acute, non-penetrating SCI

Fractures of the Spine

FRACTURES AND FRACTURE-DISLOCATIONS OF THE THORACIC AND LUMBAR SPINE
• assess ligamentous instability using flexion/extension x-ray views of C-spine ± MRI
• thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
  • anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
  • middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
  • posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspinous, and ligamentum ligaments

Types of Injury (Denis Classification)
• compression fracture (58%)
  • produced by flexion
  • posterior ligament complex (supraspinous and interspinous ligaments, ligamentum flavum, and intervertebral joint capsules) remain intact
  • fractures are stable but lead to kyphotic deformity

Pharmacological Therapy for Acute Spinal Cord Injury: Congress of Neurological Surgeons (CNS) and American Association of Neurological Surgeons (AANS) Guidelines

Introduction: This study sought to determine the relative effectiveness of early (<24 h after injury) versus late (≥24 h after injury) decompressive surgery following a traumatic cervical spinal cord injury (SCI).

Methods/Population: A prospective cohort study completed in 2002-2009 involving 6 North American institutions. Participants were 16-80 yr with a cervical SCI. Outcomes evaluated were changes in American Spinal Injury Association Impairment Scale (ASIS) grade at 6 mo follow-up, complications, and mortality.

Results: Of 313 participants enrolled, 182 underwent early surgery and 131 underwent late surgery. 222 participants were available for follow-up at 6 mo. The odds of at least 2 grade AIS improvement were greater for those who had early surgery compared to those with late surgery (OR = 2.83, 95% CI 1.10, 7.28). Mortality was observed for each group during the first 30 d post injury. No statistically significant differences were observed for complications (p=0.21).

Conclusion: Early decompression surgery following a SCI is safe and associated with higher AIS improvement at 6 mo following injury.

A New Classification of Thoracolumbar Injuries: The Importance of Injury Morphology, the Integrity of the Posterior Ligamentous Complex, and Neurological Status

Introduction: To devise a practical and comprehensive classification system to assist in clinical decision of operative or non-operative thoracolumbar injuries.

Methods/Population: Spine trauma specialists contributed factors that were deemed important for clinical decisions regarding thoracolumbar trauma. A new classification system called the Thoracolumbar Injury Classification and Severity Score (TLICS) was devised based on three parameters: 1) morphology of the injury determined radiographically, 2) integrity of posterior ligamentous complex, and 3) neurological status.

Conclusion: An easy to apply and clinically relevant decision making tool regarding thoracolumbar trauma.
• burst fracture (17%)
  ▪ stable: anterior and middle columns parted with bone retropulsed nearby
    ▪ hallmark is pedicle widening on AP x-ray
    ▪ spinal cord (seen on x-ray and CT); posterior column is uninjured
  ▪ unstable: same as the stable but with posterior column disruption (usually ligamentous)
• flexion distraction injury (6%)
  ▪ hyperflexion and distraction of posterior elements
  ▪ middle and posterior columns fail in distraction
  ▪ classic: Chance = horizontal fracture through posterior arch, pedicles, posterior vertebral body
  ▪ can be purely ligamentous, i.e. through PLL and disc
• fracture-dislocation (6%)
  ▪ anterior and cranial dislocation of superior vertebral body → 3 column failure
  ▪ three types:
    ▪ flexion-rotation
    ▪ flexion-distraction
    ▪ shear/hyperextension (rare)

Management of Thoracolumbar Injury
• severity and management based on TLICS classification

FRACTURES OF THE CERVICAL SPINE

Types of Injury
• C1 vertebral fracture (Jefferson fracture)
  ▪ vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas), pushing the lateral masses of the atlas outward and disrupting the ring of the atlas
  ▪ also can cause an occipital condylar fracture
• odontoid process fracture
  ▪ causes C1 and odontoid of C2 to move independently of C2 body
  ▪ this occurs because
    ▪ normally C1 vertebra and odontoid of C2 are a single functional unit
    ▪ alar and transverse ligaments on posterior aspect of odontoid most commonly remain intact following injury
  ▪ patients often report a feeling of instability and present holding their head with their hands
• C2 vertebral fracture (hangman fracture, traumatic spondylolisthesis of axis):
  ▪ bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3
  ▪ usually neurologically intact
• Clay-Shoveler fracture
  ▪ avulsion of spinous process, usually C6 or C7

Imaging
• AP spine x-ray (open-mouth and lateral view), CT

Treatment
• immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
• Type II and III odontoid fractures
  ▪ consider surgical fixation for comminution, displacement, or inability to maintain alignment with external immobilization
  ▪ confirm stability after recovery with flexion-extension x-rays

Neurologically Determined Death

Definition
• irreversible and diffuse brain injury resulting in absence of clinical brain function
• cardiovascular activity may persist for up to 2 wk

Criteria of Diagnosis
• prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/poisoning, temperature >32ºC, no electrolyte/acid-base/endocrine disturbance
• absent brainstem reflexes:
  ▪ absent pupillary light reflex
  ▪ absent corneal reflexes
  ▪ absent oculocephalic response
• absent caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides)
• absent pharyngeal and tracheal reflexes
• absent cough with tracheal suctioning
• absent respiratory drive at PaCO₂ >60 mmHg or >20 mmHg above baseline (apnea test)
• 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
• confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

• TLICS scoring based on morphology of injury, status of posterior ligamentous complex, and neurological status
• Non-operative management if TLICS = 0-3, operative management if TLICS = 5+, either operative or non-operative if TLICS = 4
**Coma**

**Definition**
- an unrousable state in which patients show no meaningful response to environmental stimuli

**Pathophysiology**
- lesions affecting the cerebral cortex bilaterally, the reticular activating system (RAS) or their connecting fibres
- focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures

**Classification**
- structural lesions (tumour, pus, blood, infarction, CSF): 1/3 of comas
  - supratentorial mass lesion: leads to herniation
  - infratentorial lesion: compression of or direct damage to the RAS or its projections
- metabolic disorders/diffuse hemispheric damage: 2/3 of comas
  - deficiency of essential substrates (e.g. oxygen, glucose, vitamin B₁₂)
  - exogenous toxins (e.g. drugs, heavy metals, solvents)
  - endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
  - infections (meningitis, encephalitis)
  - trauma (concussion, diffuse shea axonal damage)

**Investigations and Management**
- ABCs
- labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
- CT/MRI, LP, EEG

**Persistent Vegetative State**

**Definition**
- a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
- “awake but not aware”
- follows comatose state

**Etiology/Prognosis**
- most commonly caused by cardiac arrest or head injury
- due to irreversible loss of cerebral cortical function but intact brainstem function
- average life expectancy is 2-5 yr

**Pediatric Neurosurgery**

**Spinal Dysrampism**

**SPINA BIFIDA OCCULTA**

**Definition**
- congenital absence of a spinous process and a variable amount of lamina
- no visible exposure of meninges or neural tissue

**Epidemiology**
- 15-20% of the general population; most common at L5 or S1

**Etiology**
- failure of fusion of the posterior neural arch

**Clinical Features**
- no obvious clinical signs
- presence of lumbosacral cutaneous abnormalities (dimple, sinus, port-wine stain, or hair tuft) should increase suspicion of an underlying anomaly (lipoma, dermoid, diastematomyelia)

**Investigations**
- plain film: absence of the spinous process along with minor amounts of the neural arch
- U/S, MRI to exclude spinal anomalies

**Treatment**
- requires no treatment
MENINGOCELE (SPINA BIFIDA APERTA)

Definition
- herniation of meningeal tissue and CSF through a defect in the spine, without associated herniation of neural tissue

Etiology
- primary failure of neural tube closure

Clinical Features
- most common in lumbosacral area
- usually no disability, low incidence of associated anomalies, and hydrocephalus

Investigations
- plain films, CT, MRI, U/S, echo, GU investigations

Treatment
- surgical excision and tissue repair (excellent results)

MYELOMENINGOCELE (SPINA BIFIDA APERTA)

Definition
- herniation of meningeal and CNS tissue through a defect in the spine

Etiology
- same as meningocele

Clinical Features
- sensory and motor changes distal to anatomic level producing varying degrees of weakness
- urinary and fecal incontinence
- 65-85% of patients with myelomeningocele have hydrocephalus
- most have Type II Chiari malformation (see Chiari Malformations, NS36)

Investigations
- plain films, CT, MRI, U/S, echo, GU investigations

Treatment
- surgical closure to preserve neurologic status and prevent CNS infections
- closure in utero shown to decrease hydrocephalus and improve post natal motor scores

Prognosis
- operative mortality close to 0%, 95% 2-yr survival
- 80% have IQ >80 (but most are 80-95), 40-85% ambulatory, 3-10% have normal urinary continence
- early mortality usually due to Chiari malformation complications (respiratory arrest and aspiration), whereas late mortality is due to shunt malfunction

Intraventricular Hemorrhage

- see Pediatrics, P70

Hydrocephalus in Pediatrics

Etiology
- congenital
  - aqueductal anomalies, primary aqueductal stenosis in infancy
  - secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
  - Dandy-Walker malformation (2-4%)
  - Chiari malformation, especially Type II
  - myelomeningocele
- acquired
  - post meningitis
  - post hemorrhage (SAH, IVH)
  - masses (vascular malformation, neoplastic)

Clinical Features
- symptoms and signs of hydrocephalus are age related in pediatrics
- increased head circumference (HC), bulging anterior fontanelle, widened cranial sutures
- irritability, lethargy, poor feeding, and vomiting
- “cracked pot” sound on cranial percussion
- scalp vein dilation (increased collateral venous drainage)
- sunset sign – forced downward deviation of eyes
- episodic bradycardia and apnea
Investigations
- skull x-ray, U/S, CT, MRI, ICP monitoring

Treatment
- similar to adults (see Hydrocephalus, NS7)

Dandy-Walker Malformation

Definition
- atresia of foramina of Magendie and Luschka, resulting in:
  - complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic cerebellar hemispheres
  - posterior fossa cyst, enlarged posterior fossa
  - dilatation of 4th ventricle (also 3rd and lateral ventricles)
- associated anomalies
  - hydrocephalus (90%)
  - agenesis of corpus callosum (17%)
  - occipital encephalocele (7%)

Epidemiology
- 2-4% of pediatric hydrocephalus

Clinical Features
- 20% are asymptomatic, seizures occur in 15%
- symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
- ataxia, spasticity, poor fine motor control common in childhood

Investigations
- ultrasound, CT, MRI

Treatment
- asymptomatic patients require no treatment
- associated hydrocephalus requires surgical treatment
  - e.g. ventriculoperitoneal (VP) shunt, cystoperitoneal (CP) shunt, lumboperitoneal (LP) shunt, ventriculoatrial (VA) shunt, lumbar drain

Prognosis
- 75-100% survival, 50% have normal IQ

Chiari Malformations

Definition
- malformations at the medullary-spinal junction

Etiology
- unclear, likely maldevelopment/dysgenesis during fetal life

Figure 30. Chiari malformations
Craniosynostosis

Definition
• premature closure of the cranial suture(s)

Classification
• sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
• coronal: expansion in superior and lateral direction (brachiocephaly)
• metopic (trigonocephaly)
• lambdoid: least common

Epidemiology
• 0.6/1,000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

Clinical Features
• skull deformity, raised ICP ± hydrocephalus
• ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
• must differentiate between positional plagiocephaly (secondary to back sleeping)

Investigations
• plain radiographs, CT scan

Treatment
• parental counseling about nature of deformity, associated neurological symptoms
• surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)

Pediatric Brain Tumours

• see Tumours, NS10

Epidemiology
• 20% of all pediatric cancers (second only to leukemia)
• 60% of pediatric brain tumours are infratentorial
• pediatric brain tumours arise from various cellular lineages
  • glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma multiforme (largely supratentorial) (see Astrocytoma, NS12)
  • primitive nerve cells: supratentorial PNET
    • 90% of neonatal brain tumours, infratentorial (medulloblastoma), pineal gland (pineoblastoma)
  • non-neuronal cells: germ cell tumour, craniopharyngioma, dermoid, meningioma, neurinoma (schwannoma), pituitary adenoma, others

Clinical Features
• vomiting, seizure, macrocrania, hydrocephalus
• developmental delay, poor feeding, failure to thrive
• often initially escapes diagnosis due to expansile cranium and neural plasticity in children

### Surgical Management of Epilepsy

- see Neurology, N18 for the medical treatment of epilepsy

#### Indications
- medically refractory seizures, usually defined as seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing; other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

#### Procedure
- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common

#### Outcomes
- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

#### Morbidity
- 0.4-4% of surgical patients will have partial hemianopsia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
- most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
- the degree of memory decline stabilizes after 1-2 yr

#### Predictors
- positive predictive factors for seizure freedom following anteromedial temporal lobectomy
  - hippocampal sclerosis (unilateral)
  - focal localization of interictal epileptiform discharges
  - absence of pre-operative generalized seizures
  - tumoural cause
  - complete resection of the lesion

### Surgical Management for Trigeminal Neuralgia

- reserved for cases refractory to medical management; see Neurology, N44 for medical management

#### Surgical Options
- trigeminal nerve branch procedures
  - local blocks (phenol, alcohol)
  - neurectomy of the trigeminal branch

---

**A Randomized, Controlled Trial of Surgery for Temporal Lobe Epilepsy**
NEJM 2001;345:311-318

**Introduction:** This RCT evaluates the efficacy and safety of neurosurgery for temporal lobe epilepsy.

**Methods:** 80 patients with poorly controlled temporal lobe epilepsy were randomized for surgery (n=40) or for continued treatment with antiepileptic drugs (n=40). The primary outcome was freedom from seizures that impair awareness of self and surroundings during the period of 1 yr. Secondary outcomes included frequency and severity of seizures, quality of life, disability and death.

**Results:** The surgical group had higher cumulative proportion of patients without seizures impairing awareness compared to the medical group (p<0.01). The surgical group also had lower seizure frequency (p<0.001) and better quality of life (p<0.001). 4 patients in the surgical group had adverse effects (thalamic infarct, n=1; wound infection, n=1; verbal memory decline impairment occupation, n=2). One patient in the medical group died; no patients died in the surgical group.

**Conclusions:** In patients with poorly controlled temporal-lobe epilepsy, surgery is superior to prolonged medical therapy.
percutaneous trigeminal rhizotomy
microvascular decompression
radiofrequency thermocoagulation
Gamma Knife® radiosurgery
microvascular decompression
posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable Teflon® felt

Basic Anatomy Review

FETAL CIRCULATION

Umbilical arteries (deoxygenated blood)
Umbilical vein (oxygenated blood)
Umbilical cord
Amnion
Chorion (fetal)
Decidua (maternal)
Endometrial artery
Endometrial vein
Placenta

MATERNAL CIRCULATION

Figure 1. Placental blood flow

Placenta
- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by tissues into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG, and IGFs
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see Obstetrical Hemorrhage, OB14)

Pregnancy

Diagnosis of Pregnancy

History
- obstetrical and gynecological history
- obtain the year, location, mode of delivery, duration of labour, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format
  - Gravidaity (G)
    - G: total number of pregnancies of any gestation (multiple gestation=one pregnancy)
    - includes current pregnancy, abortions, ectopic pregnancies, and hydattidiform moles
  - Parity (TPAL)
    - T: number of term infants delivered (>37 wk)
    - P: number of premature infants delivered (20-36+6 wk)
    - A: number of abortions (loss of intrauterine pregnancy prior to viability of fetus <20 wk and/or <500 g fetal weight)
      - induced (therapeutic) and spontaneous (miscarriage)
    - L: number of living children
- symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, and fatigue

Physical Signs
- Goodell’s sign: softening of the cervix (4-6 wk)
- Chadwick’s sign: bluish discolouration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)
- Hegar’s sign: softening of the cervical isthmus (6-8 wk)
- uterine enlargement
- breast engorgement, areolae darkening, and prominent vascular patterns
- symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, and fatigue

Obstetric Hemorrhage
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see Obstetrical Hemorrhage, OB14)

GBS Group B Streptococcus
GDM gestational diabetes mellitus
GTN gestational trophoblastic neoplasia
HC head circumference
HELPP hemolysis, elevated liver enzymes, low platelets
IGF infant growth factors
IMM intramyometrial
IOD induction of labour
IPS integrated prenatal screen
IUD intrauterine fetal death
IUGR intrauterine growth restriction
IVH intraventricular hemorrhage
L/S lecithin-sphingomyelin ratio
LLDP left lateral decubitus position
LMP last menstrual period
MSAFP maternal serum ß-fetoprotein
MSS maternal serum screen
MTX methotrexate
NPT non-invasive prenatal testing
NST non-stress test
NTDs neural tube defects
NTUS nuchal translucency ultrasound
OA occiput anterior
OGTT oral glucose tolerance test
ONTD open neural tube defect
OP decidua posterior
OT occult transverse
PAPP-A pregnancy-associated plasma protein a
PG plasma glucose
PPD postpartum depression
PPH postpartum hemorrhage
PPROM preterm premature rupture of membranes
PROM premature rupture of membranes
PITL preterm labour
RDS respiratory distress syndrome
ROM rupture of membranes
SFH symphysial fundal height
SOGC Society of Obstetricians and Gynaecologists of Canada
SVD spontaneous vaginal delivery
TENS transcutaneous electrical nerve stimulation
TPN total parenteral nutrition
UTI urinary tract infection
VBAC vaginal birth after Cesarean

Umbilical Vessels
- Always check the umbilical cord for 2 arteries and 1 vein: approximately 1/3 of babies with a single uterine artery will have another anomaly, IUGR or aneuploidy
Investigations
• β-hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
  ▪ positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP
  ▪ plasma levels double every 1-2 d, peak at 8-10 wk, then fall to a plateau until delivery
    • levels less than expected suggest: ectopic pregnancy, abortion, or inaccurate dates
    • levels greater than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates
• U/S
  ▪ transvaginal
    • 5 wk amenorrhea: gestational sac visible
    • 6 wk: fetal pole visible
    • 7-8 wk: fetal heart activity visible
  ▪ transabdominal
    • 6-8 wk: intrauterine pregnancy visible (β-hCG ≥6,500 mIU/mL)

Maternal Physiologic Adaptations to Pregnancy

Table 1. Physiologic Changes During Pregnancy

| Skin | Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation) Other: spider angiomas, palmar erythema due to increased estrogen, striae gravidarum due to connective tissue changes |
| Cardiovascular | Hyper-dynamic circulation  
Increased CO, HR, and blood volume  
Decreased blood pressure due to decreased PVR and decreased venous return from enlarging uterus compressing IVC and pelvic veins  
Increased venous pressure leads to risk of varicose veins, hemorrhoids, leg edema |
| Hematologic | Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit  
Increased leukocyte count but impaired function leads to improvement in autoimmune diseases  
Gestational thrombocytopenia: mild (platelets >70,000/µL) and asymptomatic, normalizes within 2-12 wk following delivery  
Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery |
| Respiratory | Increased incidence of nasal congestion and epistaxis  
Increased O₂ consumption to meet increased metabolic requirements  
Elevated diaphragm (i.e. patient appears more "barrel-chested")  
Increased minute ventilation leads to decreased CO₂ resulting in mild respiratory alkalosis that helps CO₂ diffuse across the placenta from fetal to maternal circulation  
No change in VC and FEV₁  
Decreased TLC, FRC, and RV |
| Gastrointestinal | GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying)  
Increased gallstones due to progesterone causing increased gallbladder stasis  
Constipation and hemorrhoids due to progesterone causing decreased GI motility |
| Genitourinary | Increased urinary frequency due to increased total urinary output  
Increased incidence of UTI and pyelonephritis due to urinary stasis (see Urinary Tract Infection, OB29)  
Glycosuria that can be physiologic especially in the 3rd trimester; must test for GDM  
Ureters and renal pelvis dilation (R>L) due to progesterone-induced smooth muscle relaxation and uterine enlargement  
Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmol/L), uric acid, and BUN |
| Neurologic | Increased incidence of carpal tunnel syndrome and Bell’s palsy |
| Endocrine | Thyroid: moderate enlargement and increased basal metabolic rate  
Increased total thyroxine and thyroxine binding globulin (TBG)  
Free thyroxine index and TSH levels are normal  
Adrenal: maternal cortisol rises throughout pregnancy (total and free)  
Calcium: decreased total maternal Ca²⁺ due to decreased albumin  
Free ionized Ca²⁺ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), results in increased bone resorption and gut absorption, increased bone turnover (but no loss of bone density due to estrogen inhibition) |
**Antepartum Care**

- provided by obstetrician, family doctor, midwife, or multidisciplinary team (based on patient preference and risk factors)
- Antenatal Records (province specific)

### Preconception Counselling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
- **past medical history**: optimize illnesses and medications prior to pregnancy (see *Medical Complications of Pregnancy, OB26,* and *Medications in Pregnancy, OB11*)

#### supplementation
- folic acid: encourage diet rich in folic acid and supplement 8-12 wk preconception until end of T1 to prevent NTDs
  - 0.4-1 mg daily in all women; 5 mg if previous NTD, antiepileptic medications, DM, or BMI >35 kg/m²
- iron supplementation, prenatal vitamins

#### risk modification
- lifestyle: balanced nutrition and physical fitness
- medications: discuss teratogenicity of medications so they may be adjusted or stopped if necessary
- infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV
- genetic testing as appropriate for high risk groups (see *Prenatal Screening, Table 2*); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay or birth anomalies
- social: alcohol, smoking, street drugs, domestic violence (see *Family Medicine, FM11, FM13, FM27*)

### Initial Prenatal Visit

- usually within 8-12 wk of the first day of LMP or earlier if <20 or >35 yr old, bleeding, very nauseous, or other risk factors present
- Antenatal Records are filled out on the first prenatal visit

#### History
- gestational age by dates from the first day of the LMP
- if LMP unreliable, get a dating ultrasound which could coincide with nuchal translucency at ~12 wks
- dates should change if T1 U/S is greater than 5 days in difference from LMP due date
  - Naegle’s rule: 1st day of LMP + 7 d – 3 mo
  - e.g. LMP = 1 Apr 2014, EDC = 8 Jan 2015 (modify if cycle >28 d by adding number of d >28)
- history of present pregnancy (e.g. bleeding, N/V) and all previous pregnancies
- past medical, surgical, and gynecological history
- prescription and non-prescription medications
- family history: genetic diseases, birth defects, multiple gestation, consanguinity
- social history: smoking, alcohol, drug use, domestic violence (see *Family Medicine, FM11, FM13, FM27*)

#### Physical Exam
- complete physical exam to obtain baseline patient information
- BP and weight important for interpreting subsequent changes
- pelvic exam

#### Investigations
- blood work
  - CBC, blood group and Rh status, antibody screen, infection screening as per preconception counselling
- urine R&M, midstream urine C&S
  - screen for bacteriuria and proteinuria
- pelvic exam
  - Pap smear (only if required according to patient history and provincial screening guidelines), cervical or urine PCR for *N. gonorrhoeae* (GC) and *C. trachomatis*
Nausea and Vomiting

Epidemiology
• affects 50-90% of pregnant women
• often limited to T1 but may persist

Management
• rule out other causes of N/V
• weigh frequently, assess level of hydration, test urine for ketones
  • non-pharmacological
    ▪ avoid mixing fluids and solids, frequent small meals
    ▪ stop prenatal vitamins (folic acid must continue until >12 wk)
    ▪ increase sleep/rest
    ▪ ginger (maximum 1,000 mg/d)
    ▪ acupuncture, acupressure
  • pharmacological
    ▪ first line: Diclectin® (10 mg doxylamine succinate with vitamin B6) 4 tablets PO daily to maximum of 8 tablets
    ▪ if no improvement, try dimenhydrinate (50-100 mg q4-6h PO), followed by hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
    ▪ vitamin B6 lollipops
    ▪ if patient dehydrated, assess fluid replacement needs and resuscitate accordingly
  • severe/refractory
    ▪ consider homecare with IV fluids and parenteral anti-emetics, hospitalization

Hyperemesis Gravidarum

Definition
• intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
• affects ~1% of pregnancies

Etiology
• multifactorial with hormonal, immunologic, and psychologic components
• rapidly rising β-hCG ± estrogen levels may be implicated

Investigations
• rule out systemic causes: GI inflammation, pyelonephritis, thyrotoxicosis
• rule out obstetrical causes: multiple gestation, GTN, HELLP syndrome
• CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
• ultrasound

Management
• thiamine supplementation may be indicated
• non-pharmacological (see Nausea and Vomiting, OB5)
• pharmacological options
  ▪ Diclectin® (for dosage, see Nausea and Vomiting, OB5)
  ▪ Dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
  ▪ other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
  ▪ also consider: ondansetron or methylprednisolone
  ▪ if severe: admit to hospital, NPO initially then small frequent meals, correct hypovolemia, electrolyte disturbance, and ketosis, TPN (if very severe) to reverse catabolic state

Complications
• maternal
  ▪ dehydration, electrolyte and acid-base disturbances
  ▪ Mallory-Weiss tear
  ▪ Wernicke's encephalopathy, if protracted course
  ▪ death
• fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight
Subsequent Prenatal Visits

Timing
- for uncomplicated pregnancies, SOGC recommends q4-6wk until 30 wk, q2-3wk from 30 wk, and q1-2 from 36 wk until delivery

Assess at Every Visit
- estimated GA
- history: fetal movements, uterine bleeding, leaking, cramping, questions, concerns
- physical exam: BP, weight gain, SFH, Leopold's maneuvers (T3) for lie, position, and presentation of fetus
- investigations: urinalysis for glucosuria, proteinuria; fetal heart rate starting at 10-12 wk using Doppler U/S

Leopold's Maneuvers
- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

Small for Dates
- Date miscalculation
- IUGR
- Fetal demise
- Oligohydramnios

Large for Dates
- Date miscalculation
- Multiple gestation
- Polyhydramnios
- LGA (familial, DM)
- Fibroids

Prenatal Screening and Diagnostic Tests

Screening Tests
- testing should only occur following counselling and with the informed consent from the patient

Table 2. High-Risk Population Screening Tests

<table>
<thead>
<tr>
<th>Disease (Inheritance)</th>
<th>Population(s) at Risk</th>
<th>Screening Test(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thalassemia (AR)</td>
<td>Mediterranean, South East Asian, Western Pacific, African, Middle Eastern, Caribbean, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Sickle Cell (AR)</td>
<td>African, Caribbean, Mediterranean, Middle Eastern, Indian, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Cystic Fibrosis (CF) (AR)</td>
<td>Family history of CF in patient or partner or medical condition linked to CF like male infertility</td>
<td>CFTR gene DNA analysis</td>
</tr>
<tr>
<td>Tay Sachs Disease (AR)</td>
<td>Ashkenazi Jewish*, French Canadians, Cajun</td>
<td>Enzyme assay HEXA, or DNA analysis HEXA gene</td>
</tr>
<tr>
<td>Fragile X Syndrome (X-linked)</td>
<td>Family history – confirmed or suspected</td>
<td>DNA analysis: FMR-1 gene</td>
</tr>
</tbody>
</table>

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD), if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners positive, refer for genetic counselling.
### Table 3. Gestation-Dependent Screening Investigations

<table>
<thead>
<tr>
<th>Gestational Age (wk)</th>
<th>Investigations</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-12</td>
<td>Dating U/S, possible Pap smear, chlamydia/gonorrhea cultures, urine C&amp;S, HIV, VDRL, HepB5Ag, Parovirus IgM or IgG if high risk (small child at home or daycare worker/primary teacher), Varicella IgG if no history of disease/immunization, CBC, blood group and screen</td>
<td></td>

<td>GBS screen</td>
<td>Measures 1. MSAFP 2. β-hCG 3. Unconjugated estrogen (estriol or µE3) 4. Inhibin A</td>
</tr>
</tbody>
</table>

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen. Ideally testing for MSS and IPS Part 2 occur between 15-18 wk to give women more time to make decisions and move ahead with diagnostic testing should the resulting screen be positive.

### Ultrasound Screening
- **8-12 wk GA**: Dating Ultrasound (most accurate form of pregnancy dating)
  - measurement of crown-rump length (margin of error ± 5 d)
  - change EDC to U/S date if >5 d discrepancy from EDC based on LMP
- **11-14 wk GA**: NTUS
  - measures the amount of fluid behind the neck of the fetus
  - early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner’s syndrome)
  - NT measurement is necessary for the FTS and IPS Part 1
- **18-20 wk GA**: Growth and Anatomy U/S (margin of error ± 10 d)
  - earlier or subsequent ultrasounds performed when medically indicated

### Non-Invasive Prenatal Testing (NIPT)
- non-invasive screening for Down syndrome and other chromosomal abnormalities in spontaneous singleton pregnancies
- analyses maternal blood for circulating cell free fetal DNA (ccffDNA) at 10 wk GA

### Advantages
- high sensitivity (98-99%), FP<2%

### Disadvantages
- less sensitive for Trisomy 18 and 13
- low specificity (all positive results must be confirmed with amniocentesis)
- does not screen for oNTD
Diagnostic Tests

Indications
- age >35 yr (increased risk of chromosomal anomalies)
- risk factors in current pregnancy
  - abnormal U/S
  - abnormal prenatal screen (IPS, FTS, or MSS)
- past history/family history of
  - previous pregnancy or family history of chromosomal anomaly or genetic disease
  - either parent a known carrier of a genetic disorder or balanced translocation
  - consanguinity
  - >3 spontaneous abortions

AMNIOCENTESIS
- U/S-guided transabdominal extraction of amniotic fluid

Indications
- identification of genetic anomalies (15-16 wk gestation) as per indications above
- confirmation of positive NIPT testing
- positive FTS/IPS
- assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
  - if >2:1, RDS is less likely to occur

Advantages
- also screens for oNTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

Disadvantages
- 1/400-1/500 risk of spontaneous abortion
- results take 14-28 d; FISH can be done on chromosomes X, Y, 21, 13, 18 to give preliminary results in 48 h

CHORIONIC VILLUS SAMPLING
- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk

Advantages
- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

Disadvantages
- 1-2% risk of spontaneous abortion
- does not screen for oNTD
- 1-2% incidence of genetic mosaicism “false negative” results

Table 4. Comparison of FTS, MSS, and IPS

<table>
<thead>
<tr>
<th>FTS</th>
<th>MSS</th>
<th>IPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>11-14 wk</td>
<td>15-20 wk</td>
<td>11-13 wk U/S-Nuchal Translucency</td>
</tr>
<tr>
<td>Risk estimate for 1. Down syndrome (Trisomy 21): increased NT, increased ( \beta )-hCG</td>
<td>Risk estimate for 1. oNTD: increased MSAFP (sensitivity 80-90%)</td>
<td>Risk estimate for 1. oNTD, Trisomy 21, Trisomy 18</td>
</tr>
<tr>
<td>2. Trisomy 18: increased NT, decreased PAPP-A, decreased ( \beta )-hCG</td>
<td>2. Trisomy 21: decreased MSAFP, increased ( \beta )-hCG, decreased ( \mu )E3 (sensitivity 65%)</td>
<td>Sensitivity ~85-90%</td>
</tr>
<tr>
<td>Note: does not measure risk of open neural tube defect (oNTD) and should be combined with MSAFP at 11-13 wk</td>
<td>3. Trisomy 18: decreased MSAFP, decreased ( \beta )-hCG, decreased ( \mu )E3, decreased inhibin (sensitivity 80%)</td>
<td>2% false positive rate</td>
</tr>
<tr>
<td>More accurate estimate of Down syndrome risk than MSS, sensitivity ~85% (when combined with age)</td>
<td>Only offered alone if patient missed the time window for IPS or FTS</td>
<td>Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</td>
</tr>
<tr>
<td>5% false positive rate</td>
<td>8% baseline false positive rate for Trisomy 21, lower for oNTD and Trisomy 18</td>
<td></td>
</tr>
<tr>
<td>Patients with positive screen should be offered CVS, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</td>
<td>Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</td>
<td></td>
</tr>
</tbody>
</table>

Note: In twins, FTS, MSS, and IPS are not applicable; screen with NT for chromosomal abnormalities and MSAFP for oNTDs

Compared to CVS, amniocentesis has a higher accuracy of prenatal cytogenetic diagnosis (99.8% vs. 97.5%) and lower risk of spontaneous abortion (0.5% vs. 1-2%)

Risk Factors for Neural Tube Defects

GRIMM
- Genetics: family history of NTD (risk of having second child with NTD is increased to 2-5%), consanguinity, chromosomal (characteristic of Trisomy 13, 18, and 21)
- Race: European Caucasians > African Americans, 3-fold higher in Hispanics
- Insufficient vitamins: zinc and folate
- Maternal chronic disease (e.g. DM)
- Maternal use of antiepileptic drugs
- General population risk for NTD is 0.1%
ISOIMMUNIZATION SCREENING

Definition
• isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

Etiology
• maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
• Anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
• Risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
• sensitization routes
  • incompatible blood transfusions
  • previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, abruption)
  • invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
  • any type of abortion
  • labour and delivery

Investigations
• Screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
• Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
• detailed U/S for hydrops fetalis

Prophylaxis
• exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
• Rhogam® (300 µg) given to all Rh negative and antibody screen negative women in the following scenarios
  ▪ routinely at 28 wk GA (provides protection for ~12 wk)
  ▪ within 72 h of the birth of an Rh positive fetus
  ▪ with a positive Kleihauer-Betke test
  ▪ with any invasive procedure in pregnancy (CVS, amniocentesis)
  ▪ in ectopic pregnancy
  ▪ with miscarriage or therapeutic abortion
  ▪ with an antepartum hemorrhage
• if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy ± serial amniocentesis as needed (Rhogam® has no benefit)

Investigations
• MCA dopplers are done to assess degree of fetal anemia or if not available bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
• cordocentesis for fetal Hb should be used cautiously (not first line)

Treatment
• falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
• intrauterine transfusion of O-negative pRBCs may be required for severely affected fetus or early delivery of the fetus for exchange transfusion

Complications
• anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
• severe cases can lead to fetal hydrops (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)
Counselling of the Pregnant Woman

Nutrition

- Canada’s Food Guide to Healthy Eating suggests
  - 3-4 servings of milk products daily (greater if multiple gestation)
  - a daily caloric increase of ~100 cal/d in the 1st trimester, ~300 cal/d in the second and third trimesters and ~450 cal/d during lactation
  - daily multivitamin should be continued in the 2nd trimester for women who do not consume an adequate diet; otherwise routine vitamin supplementation is not necessary (avoid excess vitamin A)
- nutrients important during pregnancy
  - folate: 0.4 mg/d for first 12 wk (5 mg/d if high risk)
  - supports increase in blood volume, growth of maternal and fetal tissue, decreases incidence of NTD
  - foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, brussels sprouts, corn, and oranges
  - calcium: 1200-1500 mg/d
  - maintains integrity of maternal bones, skeletal development of fetus, breast milk production
  - vitamin D: 1,000 IU
  - promotes calcium absorption
  - iron: 0.8 mg/d in T1, 4-5 mg/d in T2, and >6 mg/d in T3
  - supports maternal increase in blood cell mass, supports fetal and placental tissue
  - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
  - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see Iron Deficiency Anemia, OB26)
  - essential fatty acids – supports fetal neural and visual development
  - contained in vegetable oils, margarines, peanuts, fatty fish

Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is not thought to contribute to miscarriage or preterm birth (ACOG)
- relationship between caffeine and IUGR is unknown (ACOG)
- SOGC states 1-2 cups/d are safe during pregnancy

Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- chamomiles have been reported to exhibit adverse effects on the uterus

Foodborne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - listeriosis (*Listeria monocytogenes*) and toxoplasmosis (*Toxoplasma gondii*) are of concern during pregnancy
  - avoid consumption of raw meats, fish, poultry, raw eggs, and unpasteurized dairy products
  - avoid unpasteurized soft cheeses, deli meats, smoked salmon, and pates as they may be sources of *Listeria*
  - chemical contamination of food
  - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, tilefish

Lifestyle

- exercise under physician guidance
- absolute contraindications
  - ruptured membranes, preterm labour, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28th wk, persistent 2nd or 3rd trimester bleeding, uncontrolled type I DM, uncontrolled thyroid disease, or other serious cardiovascular, respiratory, or systemic disorder
• relative contraindications
  • previous preterm birth, mild/moderate cardiovascular or respiratory disorder, anemia (Hb ≤10 g/dL), malnutrition or eating disorder, twin pregnancy after 28th wk, other significant medical conditions
• weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
• work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
• air travel is acceptable in second trimester; airline cut off for travel is 36-38 wk gestation depending on the airline to avoid giving birth on the plane
• sexual intercourse: may continue, except in patients at risk for: abortion, preterm labour, or placenta previa; breast stimulation may induce uterine activity and is discouraged in high-risk patients near term
• smoking: assist/encourage to reduce or quit smoking
  • increased risk of decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labour, stillbirth
• alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
  • fetal alcohol syndrome (see Pediatrics, P25)
• cocaine: microcephaly, growth retardation, prematurity, abruptio placenta

Medications

• most drugs cross the placenta to some extent
• very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
• use any drug with caution and only if necessary
• analgesics: acetaminophen preferable to ASA or ibuprofen

Table 5. Documented Adverse Effects, Contraindicated

</tr>
</tbody>
</table>

Immunizations

Intrapartum

• administration is dependent on the risk of infection vs. risk of immunization complications
• safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis
• avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, varicella
• contraindicated: oral typhoid

Postpartum

• rubella vaccine for all non-immune mothers
• hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
• human papillomavirus (HPV) vaccine – if meets criteria
• safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis, varicella
Radiation

- ionizing radiation exposure is considered teratogenic at high doses
  - if indicated for maternal health, should be done
- imaging not involving direct abdominal/pelvic high dosage is not associated with adverse effects
  - higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen, pelvis, lumbar spine
- most investigations involve minimal radiation exposure
- radioactive isotopes of iodine are contraindicated
- no known adverse effects from Ultrasound or MRI (long-term effects of gadolinium unknown, avoid if possible)

Antenatal Fetal Surveillance

Fetal Movements

- patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus
- if the patient is concerned about decreased fetal movement, she is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk)
- all high risk women should be told to do FM counts
  - if there is a subjective decrease in fetal movement, try drinking juice, eating, changing position, or moving to a quiet room and count for 2 h; ≥6 movements in 2 h expected
  - if there are <6 movement counts in 2 h, patient should present to labour and delivery triage

NON-STRESS TEST

Definition
- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to fetal movement (see Fetal Monitoring in Labour, OB35)

Indication
- any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being
Table 8. Classification of Antepartum Non-Stress Test

<table>
<thead>
<tr>

</tr>
<tr>
<td>Action</td>
<td>FURTHER ASSESSMENT OPTIONAL, based on total clinical picture</td>
<td>FURTHER ASSESSMENT REQUIRED</td>
<td>URGENT ACTION REQUIRED An overall assessment of the situation and further investigation with U/S or BPP is required; some situations will require delivery</td>
</tr>
</tbody>
</table>

Adapted from: SOGC, Fetal Health Surveillance: Antepartum and Intrapartum Consensus Guideline, September 2007

Operating Characteristics
- false positive rate depends on duration; false negative rate = 0.2-0.3%

Interpretation
- normal: at least 2 accelerations of FHR >15 bpm from the baseline lasting >15 s, in 20 min
- abnormal: <2 accelerations of FHR in 40 min
- if no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min
- if NST abnormal, then perform BPP

BIOPHYSICAL PROFILE

Definition
- U/S assessment of the fetus ± NST

Indications
- abnormal or atypical NST
- post-term pregnancy
- decreased fetal movement
- IUGR
- any other suggestion of fetal distress or uteroplacental insufficiency

Operating Characteristics
- false positive rate ≤30%, false negative rate = 0.1%

Table 9. Scoring of the BPP

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Reassuring (2 points)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limb Extension then Flexion</td>
<td>At least one episode of limb extension followed by flexion</td>
</tr>
<tr>
<td>AFV*</td>
<td>Fluid pocket of 2 cm in 2 axes</td>
</tr>
<tr>
<td>Movement</td>
<td>Three discrete movements</td>
</tr>
<tr>
<td>Breathing</td>
<td>At least one episode of breathing lasting at least 30 s</td>
</tr>
</tbody>
</table>

*AFV is a marker of chronic hypoxia; all other parameters indicate acute hypoxia

Interpretation
- 8: perinatal mortality rate 1:1,000; repeat BPP as clinically indicated
- 6: perinatal mortality 31:1,000; repeat BPP in 24 h
- 0-4: perinatal mortality rate 200:1,000; deliver fetus if benefits of delivery outweigh risks
### Obstetrical Hemorrhage

**Definition**
- vaginal bleeding from 20 wk to term

**Differential Diagnosis**
- bloody show (shedding of cervical mucus plug) – most common etiology in T3
- placenta previa
- abruptio placenta – most common pathological etiology in T3
- vasa previa
- cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
- uterine rupture
- other: bleeding from bowel or bladder, placenta accreta, abnormal coagulation

**Table 10. Comparison of Placenta Previa vs. Abruptio Placentae**

<td>PAINLESS</td>
<td>Usually PAINFUL</td>
</tr>
</tbody>
</table>

### Placenta Previa

**Definition**
- placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
- the distance of the placental edge from the internal os is described in “millimetres away” from the internal os or “millimetres of overlap” over the internal os
- greater than 20 millimetres of overlap over the internal os in the third trimester of pregnancy is highly predictive of the need for a C/S
- any degree of overlap after 35 wk is an indication for a C/S

**Clinical Features**
- PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously, but can become catastrophic
- mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
- physical exam
  - uterus soft and non-tender
  - presenting fetal part high or displaced
  - FHR usually normal
  - shock/anemia correspond to degree of apparent blood loss
- complications
  - fetal
    - perinatal mortality low but still higher than with a normal pregnancy
    - prematurity (bleeding often dictates early C/S)
    - intrauterine hypoxia (acute or IUGR)
    - fetal malpresentation
    - PPROM
    - risk of fetal blood loss from placenta, especially if incised during C/S
  - maternal
    - <1% maternal mortality
    - hemorrhage and hypovolemic shock, anemia, acute renal failure, pituitary necrosis (Sheehan syndrome)
    - placenta accreta – especially if previous uterine surgery, anterior placenta previa
    - hysterectomy
Investigations
• transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
• if the placenta lies between 20 mm of overlap and 20 mm away from the internal os after 20 wk, transvaginal ultrasounds should be repeated in the third trimester as continued change in the placental location is likely

Management
• goal: keep pregnancy intrauterine until the risk of delivery < risk of continuing pregnancy
• stabilize and monitor
  ▪ maternal stabilization: large bore IV with hydration, O2 for hypotensive patients
  ▪ maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
  ▪ electronic fetal monitoring
  ▪ U/S assessment: when fetal and maternal condition permit, determine fetal viability, gestational age, and placental status/position
• Rhogam® if mother is Rh negative
  ▪ Kleihauer-Betke test to determine extent of fetomaternal transfusion so that appropriate dose of Rhogam® can be given
• GA <37 wk and minimal bleeding: expectant management
  ▪ admit to hospital
  ▪ limited physical activity, no douches, enemas, or sexual intercourse
  ▪ consider corticosteroids for fetal lung maturity
• delivery when fetus is mature or hemorrhage dictates
• GA ≥37 wk, profuse bleeding, or L/S ratio is >2:1 – deliver by C/S

Abruptio Placentae
Clinical Features
• classification
  ▪ total (fetal death inevitable) vs. partial
  ▪ external/revealed/apparent: blood dissects downward toward cervix
  ▪ internal/concealed (20%): blood dissects upward toward fetus
  ▪ most are mixed
• presentation
  ▪ usually PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions
  ▪ pain: sudden onset, constant, localized to lower back and uterus
  ▪ shock/anemia out of proportion to apparent blood loss
  ▪ ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  ▪ ± coagulopathy

Complications
• fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
• maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations
• clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

Management
• maternal stabilization: large bore IV with hydration, O2 for hypotensive patients
• maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, PTT/PT, platelets, fibrinogen, FDP, type and cross match)
• EFM
• blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
• Rhogam® if Rh negative
  ▪ Kleihauer-Betke test may confirm abruption
• mild abruption:
  ▪ GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  ▪ GA ≥37 wk: stabilize and deliver
• moderate to severe abruption:
  ▪ hydrate and restore blood loss and correct coagulation defect if present
  ▪ vaginal delivery if no contraindication and no evidence of fetal or maternal distress OR fetal demise
  ▪ C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress or if vaginal delivery otherwise contraindicated
Vasa Previa

Definition
- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

Epidemiology
- 1 in 5,000 deliveries – higher in twin pregnancies

Clinical Features
- PAINLESS vaginal bleeding and fetal distress (tachy- to bradyarrhythmia)
- 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)

Investigations
- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

Management
- emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)

Obstetrical Complications

Preterm Labour

Definition
- uterine contractions intense and frequent enough to cause cervical effacement and dilation between 20 and 37 wk gestation

Etiology
- idiopathic (most common)
- maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), HTN, DM, chronic illness, mechanical factors, previous obstetric, gynecological, and abdominal surgeries, socio-environmental (poor nutrition, smoking, drugs, alcohol, stress)
- maternal-fetal: PPROM (common), polyhydramnios, placenta previa, placental abruption, or placental insufficiency
- fetal: multiple gestation, congenital abnormalities of fetus, fetal hydrops, stress
- uterine: incompetent cervix, excessive enlargement (hydramnios, multiple gestation), malformations (leiomyomas, septate uterus, mullerian duct abnormalities, fibroids)

Epidemiology
- preterm labour complicates about 12% of pregnancies, most common cause of neonatal mortality in US

Risk Factors and Prediction of PTL
- maternal risk scoring using above etiologies fails to identify up to 70% of preterm deliveries and is therefore of limited use
- prior history of spontaneous PTL: most important risk factor
- prior history cervical excisions (LEEPs/cone biopsy) or mechanical dilatation (D&C)
- cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
- identification of bacterial vaginosis (Rx metronidazole if symptomatic or high-risk for PTL) and ureaplasma urealyticum (Rx erythromycin) infections: routine screening not supported by current data but it is reasonable to screen high risk women
- family history of preterm birth
- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue functioning to maintain integrity of chorionic-decidual interface in asymptomatic women
  - positive if >50 ng/mL
  - in symptomatic women (i.e. preterm contractions), fetal fibronectin is most effectively combined with U/S detecting cervical length
  - if cervical length is not short and fetal fibronectin is negative, preterm labour is highly unlikely
Clinical Features

- regular contractions (2 in 10 min, >6/h)
- cervix >1 cm dilated, >80% effaced, or length <2.5 cm

Management

A. Initial

- transfer to appropriate facility if stable
- hydration (NS at 150 mL/h)
- bed rest in LLDP
- sedation (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BPP, position, placenta location, estimated fetal weight)
- prophylactic antibiotics; (for GBS) important to consider if PPROM (e.g. erythromycin controversial but may help to delay delivery),

B. Suppression of Labour – Tocolysis

- does not inhibit preterm labour completely, but may delay delivery (used for <48 h) to allow for betamethasone valerate (Celestone®) and/or transfer to appropriate centre for care of the premature infant
- requirements (all must be satisfied)
  - preterm labour
  - live, immature fetus, intact membranes, cervical dilatation of <4 cm
  - absence of maternal or fetal contraindications
- contraindications
  - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preeclampsia or eclampsia, chorioamnionitis
  - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
- agents
  - calcium channel blockers: nifedipine
    - 20 mg PO loading dose followed by 20 mg PO 90 min later
    - 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
    - 10 mg PO q20min x 4 doses
  - contraindications: nifedipine allergy, hypotension, hepatic dysfunction, concurrent beta-mimetics or MgSO4 use, transdermal nitrites, or other antihypertensive medications
  - prostaglandin synthesis inhibitors: indomethacin
    - 1st line for early preterm labour (<30 wk GA) or polyhydramnios
    - 50-100 mg MR loading dose followed by 50 mg q6h x 8 doses
  - magnesium sulphate was previously used for tocolysis; currently, its primary use in obstetrics is limited to neuroprotection or prevention of eclampsia
    - indicated if preterm delivery is inevitable between 24 and 31+6 wks GA for neuroprotection
    - 4 g IV loading dose followed by 1g q1h maintenance until birth

C. Enhancement of Fetal Pulmonary Maturity

- betamethasone valerate (Celestone®) 12 mg IM q24h x 2 doses or dexamethasone 6 mg IM q12h x 4 doses
  - 28–34 wk GA: reduces incidence of RDS
  - 24–28 wk GA: reduces severity of RDS, overall mortality and rate of IVH
  - specific maternal contraindications: active TB

D. Cervical Cerclage

- definition: placement of cervical sutures at the level of the internal os, usually at the end of the first trimester or in the second trimester and removed in the third trimester
- indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
  - emerging evidence indicates that progesterone suppositories are superior to cerclage in preventing preterm labour not due to cervical incompetence; (neither is effective in multiple gestations)
- diagnosis of cervical incompetence
  - obstetrical Hx: silent cervical dilatation, 2nd trimester losses, procedures on cervix
  - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
- proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)

Prognosis

- prematurity is the leading cause of perinatal morbidity and mortality
  - 30 wk or 1,500 g (3.3 lb) = 90% survival
  - 33 wk or 2,000 g (4.4 lb) = 99% survival
- morbidity due to asphyxia, hypoxia, sepsis, RDS, intraventricular cerebral hemorrhage, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

Conclusions

- although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPROM, as there was an increase in maternal chorioamnionitis without significant benefits to the infant.
Prevention of Preterm Labour
• currently there are no agents approved by Health Canada to arrest preterm labour
• preventative measures: good prenatal care, identify pregnancies at risk, treat silent vaginal infection or UTI, patient education
• transvaginal ultrasound of cervical length is recommended only for high-risk pregnancies and only before 30 weeks GA

Premature Rupture of Membranes

Definitions
• PROM: rupture of membranes prior to labour at any GA
• prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
• preterm ROM: ROM occurring before 37 wk gestation
• PPROM: rupture of membranes before 37 wk AND prior to onset of labour

Risk Factors
• maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
• fetal: congenital anomaly, multiple gestation
• other risk factors associated with PTL

Clinical Features
• history of fluid gush or continued leakage

Investigations
• sterile speculum exam (avoid introduction of infection)
  ▪ pooling of fluid in the posterior fornix
  ▪ may observe fluid leaking out of cervix on cough/Valsalva (“cascade”)
• nitrazine (amniotic fluid turns nitrazine paper blue)
  ▪ low specificity as can be positive with blood, urine, or semen
• ferning (high salt in amniotic fluid evaporates, looks like ferns under microscope)
  ▪ U/S to rule out fetal anomalies, assess GA, and BPP
• cultures (lower vagina for GBS)
• L/S ratio (Lecithin:Sphingomyelin Ratio)
  ▪ consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <32 wk and no evidence of infection
  ▪ consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
  ▪ studies show broad spectrum coverage increases the time to onset of labour from PROM by 5-7 d with no increase in maternal or neonatal morbidity or mortality
• deliver urgently if evidence of fetal distress and/or chorioamnionitis

Management
• admit for expectant management and monitor vitals q4h, daily BPP and WBC count
• avoid introducing infection with examinations (do NOT do a bimanual exam)
• cultures (lower vagina for GBS)
• assess fetal lung maturity by L/S ratio of amniotic fluid
  ▪ consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <32 wk and no evidence of infection
  ▪ consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
  ▪ studies show broad spectrum coverage increases the time to onset of labour from PROM by 5-7 d with no increase in maternal or neonatal morbidity or mortality
• deliver urgently if evidence of fetal distress and/or chorioamnionitis

<td>“Grey zone” where risk of death from RDS and neonatal sepsis is the same</td>
</tr>
<tr>
<td>≥37 wk</td>
<td>Induction of labour since the risk of death from sepsis is greater than RDS</td>
</tr>
</tbody>
</table>

Prognosis
• varies with gestational age
• 90% of women with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
• 50% of women with PROM at <26 wk GA go into spontaneous labour within 1 wk
• complications: cord prolapse, intrauterine infection (choorioamnionitis), premature delivery, limb contracture
Prolonged Pregnancy

Definition
• pregnancy >42 wk GA

Epidemiology
• 41 wk GA: up to 27%
• >42 wk GA: 5.5%

Etiology
• most cases idiopathic
• anencephalic fetus with no pituitary gland
• placental sulfatase deficiency (X-linked recessive condition in 1/2,000-1/6,000 infants) – rare

Clinical Features
• postmaturity syndrome (10-20% of post-term pregnancies): fetal weight loss, reduced subcutaneous fat, scaling, dry skin from placental insufficiency, long thin body, open-eyed, alert and worried look, long nails, palms and soles wrinkled)
• with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries, pneumonia, seizures, and requirement of NICU admission

Management
• GA 40-41 wk: expectant management
  • no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
• GA >41 wk: offer IOL if vaginal delivery is not contraindicated
  • IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia, and death when compared with expectant management
• GA >41 wk and expectant management elected: serial fetal surveillance
  • fetal movement count by the mother
  • BPP q3-4d
  • if AFI is decreased, labour should be induced

Prognosis
• if >42 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
• morbidity increased with HTN in pregnancy, DM, abruption, IU/GR, and multiple gestation

Intrauterine Fetal Death

Definition
• fetal death in utero after 20 wk GA

Epidemiology
• 1% of pregnancies

Etiology
• 50% idiopathic
• 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, APS

Clinical Features
• decreased perception of fetal movement by mother
• SFH and maternal weight not increasing
• absent fetal heart tones on Doppler(not diagnostic)
• high MSAFP
• on U/S: no fetal heart rate. Depending on timing of death may see skull collapse, brain tissue retraction, empty fetal bladder, non-filled aorta, poor visualization of midline flax

Management
• diagnosis: absent cardiac activity and fetal movement on U/S required for diagnosis
• determine secondary cause
  • maternal: HbA1c, fasting glucose, TSH, Kleihauer-Betke, VDRL, ANA, CBC, anticardiolipins, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, TORCH screen
  • fetal: karyotype, cord blood, skin biopsy, genetics evaluation, autopsy, amniotic fluid culture for CMV, parvovirus B19, herpes
  • placenta: pathology, bacterial cultures

DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors

Obstetrical Causes
• Abortion
• Gestational HTN
• Fetal demise
• PPH

DIC-specific Blood Work
• Platelets
• aPTT and PT
• FDP
• Fibrinogen

Treatment
• Treat underlying cause
• Supportive
  • Fluids
  • Blood products
    • FFP, platelets, cryoprecipitate
  • Consider anti-coagulation as VTE prophylaxis
**Intrauterine Growth Restriction**

**Definition**
- infant weight <10th percentile for GA or <2,500 g

**Etiology/Risk Factors**
- 50% unknown
- maternal causes
  - malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, type 1 DM, SLE, pulmonary insufficiency, previous IUGR (25% risk, most important risk factor), chronic HTN
- maternal-fetal
  - any disease causing placental insufficiency
  - includes gestational HTN, chronic renal insufficiency, gross placental morphological abnormalities (infarction, hemangiomas, placenta previa, placenta accreta, abnormal cord insertion), prolonged gestation
- fetal causes
  - TORCH infections, multiple gestation, congenital anomalies / chromosomal abnormalities (10%)”

**Clinical Features**
- symmetric/type I (25-30%): occurs early in pregnancy
  - reduced growth of both head and abdomen
  - head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
  - usually associated with congenital anomalies or TORCH infections
- asymmetric/type II (70%): occurs late in pregnancy
  - fetal abdomen is disproportionately smaller than fetal head
  - brain is spared, therefore head:abdomen ratio increased
  - usually associated with placental insufficiency
  - more favourable prognosis than type I
- complications
  - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, hypocalcemia, hyperphosphatemia hyponatremia, and mental retardation
  - greater risk of perinatal morbidity and mortality

**Investigations**
- SFH measurements at every antepartum visit
- if mother at high risk or SFH lags >2 cm behind GA
  - U/S for biparietal diameter, head and abdominal circumference ratio, femur length, fetal weight, and AFV (decrease associated with IUGR)
  - ± BPP
  - Doppler analysis of umbilical cord blood flow

**Management**
- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
- bed rest in LLDP
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
- liberal use of C/S since IUGR fetus withstands labour poorly

---

**Macrosomia**

**Definition**
- infant weight >90th percentile for a particular GA or >4,000 g

**Etiology/Risk Factors**
- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity
Clinical Features
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Table 15, OB28)

Investigations
- serial SFH
- further investigations if mother at high risk or SFH >2 cm ahead of GA
- U/S predictors
  - polyhydramnios
  - third trimester AC >1.5 cm/wk
  - HC/AC ratio <10th percentile
  - FL/AC ratio <20th percentile

Management
- prophylactic C/S is a reasonable option where EFW >5,000 g in non-diabetic woman and EFW >4,500 g in diabetic woman
- no evidence that prophylactic C/S improves outcomes
- early induction of labour is not recommended for non-diabetic mothers
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, as current research is unclear

---

Pregnancy Complications
Multi-Fetal Gestation and Malpresentation

**Epidemiology**
- incidence of twins is 1/80 and triplets 1/6,400 in North America
- 2/3 of twins are dizygotic (fraternal)
  - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, ethnicity (e.g. certain African regions)
- monozygous twinning occurs at a constant rate worldwide (1/250)
- determine zygosity by number of placentas, thickness of membranes, sex, blood type

**Clinical Features**

**Table 13. Complications Associated with Multiple Gestation**

<td>Cord anomalies (velamentous insertion, 2 vessel cord)</td>
<td>Twin interlocking (twin A breech, twin B vertex)</td>
</tr>
</tbody>
</table>

*Most common cause of perinatal mortality in multiple gestation

**Management**
- U/S determination of chorionicity must be done within first trimester (ideally 8-12 wk GA)
- increased antenatal surveillance
  - serial U/S q 2-3wk from 24 wk GA to assess growth (uncomplicated diamniotic dichorionic)
  - increased frequency of ultrasounds in monochorionic diamniotic and monochorionic monoamniotic twins
  - Doppler flow studies weekly if discordant fetal growth (>30%)
  - BPP as needed
- may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 15% of cases have twin A delivered vaginally and twin B delivered by C/S)
- mode of delivery depends on fetal weight, GA, presentation

**Figure 4. Classification of twin pregnancies**

*Indicates time of cleavage
**Twin-Twin Transfusion Syndrome**

**Epidemiology**
- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

**Etiology**
- arterial blood from donor twin passes through placenta into vein of recipient twin

**Clinical Features**
- donor twin: IUGR, hypovolemia, hypotension, anemia, oligohydramnios
- recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, kernicterus in neonatal period

**Investigations**
- detected by U/S screening, Doppler flow analysis

**Management**
- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary
- laparoscopic occlusion of placental vessels

---

**Breech Presentation**

**Definition**
- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): hips and knees both flexed
- frank (60%): hips flexed, knees extended, buttocks present at cervix
  - most common type of breech presentation
  - most common breech presentation to be delivered vaginally
- incomplete (30%): both or one hip flexed and both or one knee present below the buttocks, feet or knees present first (footling breech, kneeling breech)

**Epidemiology**
- occurs in 3-4% of pregnancies at term (25% <28 wk)

**Risk Factors**
- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumours, fibroids, previous breech), pelvic tumours causing compression, grand multiparity
- maternal-fetal: placenta (previa), amniotic fluid (poly-/oligohydramnios)
- fetal: prematurity, multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy, hydrocephalus, anencephalus

**Management**
- ECV: repositioning of singleton fetus within uterus under U/S guidance
  - overall success rate of 65%
  - criteria: >36 wk GA, singleton, unengaged presenting part, reactive NST, not in labour
  - contraindications: previous T3 bleed, prior classical C/S, previous myomectomy, oligohydramnios, PROM, placenta previa, abnormal U/S, suspected IUGR, HTN, uteroplacental insufficiency, nuchal cord
  - risks: abruption, cord compression, cord accident, ROM, labour, fetal bradycardia requiring C/S (<1% risk), alloimmunization, fetal death 1:5,000
  - method: tocometry, followed by U/S guided transabdominal manipulation of fetus with constant fetal heart monitoring
  - if patient Rh negative, give Rhogam® prior to procedure
  - good prognostic factors (for a successful version)
    - multiparous, good fluid volume, small baby, skilled obstetrician, posterior placenta
    - pre- or early labour ultrasound to assess type of breech presentation, fetal growth, estimated weight, placenta position, attitude of fetal head (flexed is preferable); if ultrasound unavailable, recommend C/S
- ECV and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent
- method for vaginal breech delivery
  - encourage effective maternal pushing efforts
  - at delivery of after-coming head, assistant must apply suprapubic pressure to flex and engage fetal head
  - delivery can be spontaneous or assisted; avoid fetal traction
  - apply fetal manipulation only after spontaneous delivery to level of umbilicus

---

**Figure 5. Types of breech presentation**

**Criteria for Vaginal Breech Delivery**
- Frank or complete breech, GA >36 wk
- EFW 2,500-3,800 g based on clinical and U/S assessment (5.5–8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- 2 experienced obstetricians, assistant, and anesthetist present
- Ability to perform emergency C/S within 30 min if required
Vaginal Delivery of Breech Presentation
SOGC Clinical Practice Guidelines 2009;226:557-566
Objective: To discuss risks and benefits of trial of labour versus planned C/S, with selection criteria, management, and delivery techniques for trial of vaginal breech birth.
Evidence: Randomized trials, prospective cohort studies and select cohort studies from Medline search for long-term outcomes and epidemiology of vaginal breech delivery.
Summary: Higher risk of perinatal mortality and short-term neonatal morbidity can be associated with vaginal breech birth as compared to elective C/S. However, careful case selection (including term singleton breech fetuses and clinically adequate maternal pelvis) and labour management may achieve a similar safety level as elective C/S (~2 per 1,000 births perinatal mortality, ~2% short-term neonatal morbidity). Specific protocols for vaginal breech delivery should be followed: continuous fetal heart monitoring, assessment for adequate progress in labour, no induction of labour recommended, emergency C/S available, if required, and health care providers with requisite skills and experience. Informed consent for the preferred delivery method should be obtained.

Hypertensive Disorders of Pregnancy

Hypertension in Pregnancy

• hypertensive disorders of pregnancy are classified as either pre-existing or gestational HTN

PRE-EXISTING HYPERTENSION

Definition
• BP >140/90 prior to 20 wk GA, persisting >7 wk postpartum
• essential HTN is associated with an increased risk of gestational HTN, abruptio placentae, IUGR, and IUFD

GESTATIONAL HTN

Definition
• sBP >140 or dBP >90 developing after 20th wk GA in a woman known to be normotensive before pregnancy

Risk Factors
• maternal factors
  ▪ primigravida (80-90% of gestational HTN)
  ▪ first conception with a new partner
  ▪ PMHx or FHx of gestational HTN
  ▪ DM, chronic HTN, or renal insufficiency
  ▪ antiphospholipid syndrome
  ▪ extremes of maternal age (<18 or >35 yr)
  ▪ previous stillbirth or IUFD
• fetal factors
  ▪ IUGR or oligohydramnios
  ▪ GTN
  ▪ multiple gestation
  ▪ fetal hydrops

Clinical Evaluation of HTN in Pregnancy
• in general, clinical evaluation should include the mother and fetus
  • evaluation of mother
    ▪ body weight
    ▪ central nervous system
      ▪ presence and severity of headache
      ▪ visual disturbances – blurring, scotomata
      ▪ tremulousness, irritability, somnolence
      ▪ hyperreflexia
    ▪ hematologic
      ▪ bleeding, petechiae
    ▪ hepatic
      ▪ RUQ or epigastric pain
      ▪ severe N/V
    ▪ renal
      ▪ urine output and colour
      ▪ non-dependent edema (i.e. hands and face)
  • evaluation of fetus
    ▪ fetal movement
    ▪ fetal heart rate tracing – NST
    ▪ ultrasound for growth
    ▪ BPP
    ▪ Doppler flow studies

Adverse Maternal Conditions
• sBP >160 mmHg
• dBP >100 mmHg
• HELLP
• Cerebral hemorrhage
• Renal dysfunction: oliguria <500 mL/d
• Left ventricular failure, pulmonary edema
• Placental abruption, DIC

Symptoms
• Abdominal pain, N/V
• Headaches, visual problems
• SOB, chest pain
• Eclampsia: convulsions

Adverse Fetal Conditions
• IUGR
• Oligohydramnios
• Absent/reversed umbilical artery end diastolic flow

Can result in:
• Fetal disability and/or death

Ominous Symptoms of HTN in Pregnancy
RUQ pain, headache, and visual disturbances

Hypertension in Pregnancy

Adverse Maternal Conditions
• sBP >160 mmHg
• dBP >100 mmHg
• HELLP
• Cerebral hemorrhage
• Renal dysfunction: oliguria <500 mL/d
• Left ventricular failure, pulmonary edema
• Placental abruption, DIC

Symptoms
• Abdominal pain, N/V
• Headaches, visual problems
• SOB, chest pain
• Eclampsia: convulsions

Adverse Fetal Conditions
• IUGR
• Oligohydramnios
• Absent/reversed umbilical artery end diastolic flow

Can result in:
• Fetal disability and/or death
Laboratory Evaluation of Gestational Hypertension
- CBC
- PTT, INR, fibrinogen – especially if surgery or regional anesthetics are planned
- ALT, AST
- creatinine, uric acid
- 24 h urine collection for protein or albumin:creatinine ratio

Complications
- maternal
  - liver and renal dysfunction
  - seizure
  - abruptio placenta
  - left ventricular failure/pulmonary edema
  - DIC (release of placental thromboplastin consumptive coagulopathy)
  - HELLP syndrome
- treat with FFP infusion or plasma exchange
- hemorrhagic stroke (50% of deaths)
- fetal
  - IUGR, prematurity, abruptio placenta, IUFD

Management
- for non-severe HTN (149-159/90-105) target a BP of 130-155/80-105 in women without comorbidities or <140/90 in women with comorbidities
- for both pre-existing and gestational HTN, labetalol 100-400 mg PO bid-tid, nifedipine XL preparation 20-60 mg PO od, or α-methyldopa 250-300 mg PO bid-qid
- for severe HTN (BP>160/110), give one of:
  - labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg)(then switch to oral)
  - nifedipine 5-10 mg capsule q30min
  - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)
- no ACEI, ARBs, diuretics, prazosin, or atenolol
- pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk then decide to induce shortly thereafter

PREECLAMPSIA

Definition
- pre-existing or gestational HTN with new onset proteinuria or adverse conditions

Risk Factors
- nulliparity
- preeclampsia in a previous pregnancy
- age >40 yr or <18 yr
- FHx of preeclampsia
- chronic HTN
- chronic renal disease
- antiphospholipid antibody syndrome or inherited thrombophilia
- vascular or connective tissue disease
- DM (pre-gestational and gestational)
- high BMI
- hydrops fetalis
- unexplained fetal growth restriction
- abruptio placenta
- there is a potential for further deterioration to severe preeclampsia as defined above
- the adverse conditions are many and include both maternal and fetal issues

Management
- depends on GA, possible threat of seizures (check reflexes)
- if stable and no adverse factors, may admit and follow, ± decide to deliver as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
- for severe preeclampsia, stabilize and deliver
- if severe preeclampsia during labour, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
- antihypertensive therapy
  - labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg)(then switch to oral)
  - nifedipine 5-10 mg capsule q30min
  - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)
• seizure prevention
  • MgSO₄
  • postpartum management
  • risk of seizure highest in first 24 h postpartum – continue MgSO₄ for 12-24 h after delivery
  • vitals q1h
  • consider HELLP syndrome in toxic patients
  • most return to a normotensive BP within 2 wk

ECLAMPSIA

Definition
• the occurrence of one or more generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology
• an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

Risk Factors
• same as risk factors for preeclampsia

Clinical Manifestations
• eclampsia is a clinical diagnosis
• typically tonic-clonic and lasting 60-75 s
• one of the signs of an impending seizure is hyperreflexia
• symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
• in up to one third of cases, there is no proteinuria or blood pressure <140/90 mmHg prior to the seizure
• in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Management
• ABCs
• roll patient into LLDP
• supplemental O₂ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
• aggressive antihypertensive therapy for sustained diastolic pressures ≥105 mmHg or systolic blood pressures ≥160 mmHg with hydralazine or labetalol
• prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
• MgSO₄ is now the drug of choice, with previously used agents including diazepam and phenytoin
• the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
• mode of delivery is dependent on clinical situation and fetal-maternal condition

</tbody>
</table>

Diabetes Mellitus

Epidemiology
- 2-4% of pregnancies are complicated by DM

Classification of Diabetes Mellitus
- type 1 and type 2 DM (see Endocrinology, E7)
- GDM: onset of DM during pregnancy (usually around 24-28 wk GA)

Etiology
- type 1 and type 2 DM
- GDM: anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → leading to GDM and/or exacerbating pre-existing DM

MANAGEMENT

A. TYPE 1 and TYPE 2 DM

Preconception
- pre-plan and refer to high-risk clinic
- optimize glycemic control
- counsel patient on potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, CAD

Pregnancy
- if already on oral medication, generally switch to insulin therapy
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral anti-hyperglycemics
- tight glycemic control
  - insulin dosage may need to be adjusted in T2 due to increased demand and increased insulin resistance
- monitor as for normal pregnancy plus initial 24 h urine protein and creatinine clearance, retinal exam, HbA1c
  - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
  - increased fetal surveillance (BPP, NST), consider fetal ECHO to look for cardiac abnormalities

Labour
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose, and blood pressure control)
- can wait for spontaneous labour if blood glucose well-controlled and BPP normal
- induce by 38 wk
• type of delivery
  ▪ increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4,000 g (8.8 lbs)
  ▪ elective C/S for predicted birthweight >4,500 g (9.9 lbs) (controversial)
• monitoring
  ▪ during labour monitor blood glucose q1h with patient on insulin and dextrose drip
  ▪ aim for blood glucose between 3.5-6.5 mmol/L to reduce the risk of neonatal hypoglycemia

Postpartum
• insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
• no insulin is required for 48-72 h postpartum in most type 1 DM
• monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

B. GESTATIONAL DM

Screening and Diagnosis
• all pregnant women between 24-28 wk GA (or at any stage if high risk)
• 2 screening options
  ▪ 1-step screening with fasting 75 g OGTT; GDM if ≥1 of:
    ▪ FPG ≥ 5.1 mmol/L
    ▪ 1h PG ≥ 10.0 mmol/L
    ▪ 2h PG ≥ 8.5 mmol/L
  ▪ 2-step screening
    ▪ Step 1: Perform a random nonfasting 50 g OGCT
      – 1h PG < 7.8 mmol/L is normal
      – 1h PG ≥ 11.1 mmol/L is GDM
      – if 1h PG 7.8-11.0 mmol/L, proceed to Step 2
    ▪ Step 2: Perform a fasting 75 g OGTT, GDM if ≥1 of:
      – FPG ≥ 5.3 mmol/L
      – 1h PG ≥ 10.6 mmol/L
      – 2h PG ≥ 9.0 mmol/L

Management
• first line is management through diet modification and increased physical activity
• initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
• glycemic targets: FPG <5.3 mmol/L, 1h PG <7.8 mmol/L, 2h PG <6.7 mmol/L
• use of oral agents can be used in pregnancy but is off-label and should be discussed with patient
• stop insulin and diabetic diet postpartum
• 6 wk postpartum visit: follow up with 75 g OGTT, counsel about lifestyle modifications, and perform glucose challenge test q2 yr

Prognosis
• most maternal and fetal complications are related to hyperglycemia and its effects

Long-Term Maternal Complications
• type 1 and type 2 DM: risk of progressive retinopathy and nephropathy
• GDM: 50% risk of developing type 2 DM in next 20 yr

</tbody>
</table>

**Group B Streptococcus**

**Epidemiology**
- 15–40% vaginal carrier rate

**Risk Factors (for neonatal disease)**
- GBS bacteriuria during current pregnancy even if treated
- previous infant with invasive GBS infection
- preterm labour <37 wk
- ruptured membranes >18 h before delivery
- intrapartum maternal temperature ≥38°C
- positive GBS screen during current pregnancy

**Clinical Features**
- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

**Investigations**
- offer screening to all women at 35–37 wk with vaginal and anorectal swabs for GBS culture

**Treatment**
- treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- indications for antibiotic prophylaxis: positive GBS screen, GBS in urine, or previous infant with GBS disease or GBS status unknown and one of the other risk factors
- antibiotics for GBS prophylaxis
  - penicillin G 5 million units IV then 2.5 million units IV q4h until delivery
  - penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
  - penicillin allergic and at risk for anaphylaxis: vancomycin 1 g IV q12h until delivery
- if fever, broad spectrum antibiotic coverage is advised

**Urinary Tract Infection**

**Epidemiology**
- most common medical complication of pregnancy
- asymptomatic bacteriuria in 2–7% of pregnant women, more frequently in multiparous women
- note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis and preterm labour

**Etiology**
- increased urinary stasis from mechanical and hormonal (progesterone) factors
- organisms include GBS as well as those that occur in non-pregnant women

**Clinical Features**
- may be asymptomatic
- dysuria, urgency, and frequency in cystitis
- fever, flank pain, and costovertebral angle tenderness in pyelonephritis

**Investigations**
- urinalysis, urine C&S
- cystoscopy and renal function tests in recurrent infections
### Infections During Pregnancy

</tr>
</tbody>
</table>

### Management
- uncomplicated UTI
  - first line: amoxicillin (250-500 mg PO q8h x 7 d)
  - alternatives: nitrofurantoin (100 mg PO bid x 7 d)
  - follow with monthly urine cultures
- pyelonephritis
  - hospitalization and IV antibiotics

### Prognosis
- complications if untreated: acute cystitis, pyelonephritis, and possible preterm labour
- recurrence is common

<td>Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission</td>
</tr>
</tbody>
</table>

* Indicates TORCH infection

Venous Thromboembolism

Epidemiology
- incidence of 12.1/10,000 (DVT), and 5.4/10,000 (PE)
- increased risk VTE throughout pregnancy with highest risk of DVT in third trimester and postpartum period and highest risk of PE post-partum (first 6 weeks)

Risk Factors
- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, thrombophilias (see Hematology, H35)

Table 17. Risk Factors for VTE Specific to Pregnancy

<td>50% decrease in venous flow in lower extremity by T3</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Uterus is mechanical impediment to venous return</td>
<td></td>
</tr>
</tbody>
</table>

Clinical Features
- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific (as in non-pregnant women)
- unexplained spontaneous fetal loss

Investigations
- duplex venous Doppler sonography for DVT
- CXR and V/Q scan or spiral CT for PE

Management
- before initiating treatment, obtain a baseline CBC including platelets, and aPTT
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- unfractionated heparin
  - bolus of 5,000 IU followed by an infusion of ~30,000 IU/24h
  - measure aPTT 6 h after the bolus
Normal Labour and Delivery

Definition of Labour

- true labour: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
  - preterm (>20 to <36+6 wk GA)
  - term (37-41+6 wk GA)
  - postterm (>42 wk GA)
- false labour: Braxton-Hicks contractions
  - irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any cervical dilatation, effacement, or descent

The Cervix

- dilatation: latent phase: 0-4 cm (variable time); active phase: 4-10 cm
- effacement: thinning of the cervix by percentage or length of cervix (cm)
- consistency: firm vs. soft
- position: posterior vs. anterior
- application: contact between the cervix and presenting part (i.e. well or poorly applied)
  - see Bishop score (Table 22, OB38)

The Fetus

- fetal lie
  - orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, oblique)

- fetal presentation
  - fetal body part closest to the birth canal
    - breech (complete, frank, footling) (see Figure 5, OB23)
    - cephalic (vertex/occiput, face, asynclitic, brow)
    - transverse (shoulder)
  - compound (fetal extremity prolapses along with presenting part)
  - all except vertex are considered malpresentations (see Obstetrical Complications, OB16)

- fetal position
  - position of presenting part of the fetus relative to the maternal pelvis
    - OA: most common presentation (“normal”) – left OA most common
    - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour
    - OT: leads to arrest of dilatation
  - normally, fetal head enters maternal pelvis and engages in OT position
  - subsequently rotates to OA position (or OP in a small percentage of cases)

- attitude
  - flexion/extension of fetal head relative to shoulders
    - brow presentation: head partially extended (requires C/S)
    - face presentation: head fully extended
      - mentum posterior always requires C/S, mentum anterior will deliver vaginally
• station
  - position of presenting part relative to ischial spines – determined by vaginal exam
    - at ischial spines = station 0 = engaged
    - -5 to -1 cm above ischial spines or
    - +1 to +5 cm below ischial spines
    - alternatively stations can be placed on a scale from -3 to +3

Four Stages of Labour

First Stage of Labour
• latent phase
  - uterine contractions typically infrequent and irregular
  - slow cervical dilatation (usually to 4 cm) and effacement
• active phase
  - rapid cervical dilatation to full dilatation (nulliparous ≥1.0 cm/h, multiparous ≥1.2 cm/h)
  - phase of maximum slope on cervical dilatation curve
  - painful, regular contractions q2-3min, lasting 45-60 s
  - contractions strongest at fundus, weakest at lower segment

Second Stage of Labour
• from full dilatation to delivery of the baby, duration varies based on parity, contraction quality, and type of analgesia
• mother feels a desire to bear down and push with each contraction
• women may choose a comfortable position that enhances pushing efforts and delivery
  - upright (semi-sitting, squatting) and LLDP are supported in the literature
• progress measured by descent

Third Stage of Labour
• from baby’s birth to separation and expulsion of the placenta
• can last up to 30 min before intervention indicated
• demonstrated by gush of fresh blood, umbilical cord lengthening, uterine fundus changing shape (firm and globular) and rising upward
• start oxytocin IV drip, or give 10 U IM or 5 mg IV push after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
• routine oxytocin administration in third stage of labour can reduce the risk of PPH by >40%

Course of Normal Labour
<table>

<td>5-30 min</td>
</tr>
<tr>
<td>Third</td>
<td>5-30 min</td>
<td>5-30 min</td>
</tr>
</tbody>
</table>

Signs of Placental Separation
• Gush of blood
• Lengthening of cord
• Uterus becomes globular
• Fundus rises
Fourth Stage of Labour

- first postpartum hour
- monitor vital signs and bleeding, repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

The Cardinal Movements of the Fetus During Delivery

1. Head floating, before engagement
2. Engagement, descent, flexion
3. Further descent, internal rotation
4. Complete rotation, beginning extension
5. Complete extension
6. Restitution (external rotation)
7. Delivery of anterior shoulder
8. Delivery of posterior shoulder

Figure 7. Cardinal movements of fetus during delivery
Adapted from illustration in Williams Obstetrics, 19th ed

Analgesic and Anesthetic Techniques in Labour and Birth

- pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

Non-Pharmacologic Pain Relief Techniques

- reduction of painful stimuli
  - maternal movement, position change, counter-pressure, abdominal compression
- activation of peripheral sensory receptors
  - superficial heat and cold
  - immersion in water during labour
  - touch and massage, acupuncture, and acupressure
  - TENS
  - intradermal injection of sterile water
  - aromatherapy
- enhancement of descending inhibitory pathways
  - attention focusing and distraction
  - hypnosis
  - music and audio analgesia
  - biofeedback

Pharmacologic Methods (see Anesthesia and Perioperative Medicine, A2)

- nitrous oxide (e.g. self-administered Entonox®)
- narcotics (usually combined with anti-emetic)
- pudendal nerve block
- perineal infiltration with local anesthetic
- regional anesthesia (epidural block, combined spinal-epidural, spinal)
**Fetal Monitoring in Labour**

- **see online Fetal Heart Rate Tutorial**

**Vaginal Exam**

- membrane status
- cervical effacement (thinning), dilatation, consistency, position, application
- fetal presenting part, position, station
- bony pelvis size and shape
- monitor progress of labour at regular intervals and document in a partogram

**Intrapartum Fetal Monitoring**

- intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, and labour which is induced or augmented, meconium present, multiple gestation/fetal complication
  - use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate when used routinely in all patients (ie no risk factors)
  - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

**Fetal Scalp Blood Sampling**

- cervix must be adequately dilated
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns, including unexplained low variability, repetitive late decelerations, complex variable decelerations, fetal cardiac arrhythmias

Done by measuring pH or more recently fetal lactate
  - pH ≥7.25: normal, repeat if abnormal FHR persists
  - pH 7.21-7.24: repeat assessment in 30 min or consider delivery if rapid fall since last sample
  - pH ≤7.20: indicates fetal acidosis, delivery is indicated

- contraindications
  - known or suspected fetal blood dyscrasia (hemophilia, von Willebrand disease)
  - active maternal infection (HIV, genital herpes)

**Electronic FHR Monitoring**

- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)

- **Baseline FHR**
  - normal range is 110-160 bpm
  - parameter of fetal well-being vs. distress

- **Variability**
  - physiologic variability is a normal characteristic of FHR
  - variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), marked (>25 bpm)
  - normal variability indicates fetal acid-base status is acceptable
  - can only be assessed by electronic fetal monitoring (CTG)
  - variability decreases intermittently even in healthy fetus
  - see Table 19, OB36

- **Periodicity**
  - accelerations: increase of ≥15 bpm for ≥15 s, in response to fetal movement or uterine contraction (or ≥10 bpm for ≥10 s if <32 wk GA)
  - decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

**Approach to the Management of Abnormal FHR**

- **POISON – ER**
  - **P**osition (left lateral decubitus position)
  - **O**2 (100% by mask)
  - **I**V fluids (corrects maternal hypotension)
  - **F**etal scalp stimulation
  - **S**calp electrode
  - **C**hange maternal position
  - **O**xytocin
  - **N**otify MD
  - vaginal exam to rule out cord prolapse
  - rule out fever, dehydration, drug effects, prematurity
  - if above fails, consider C/S
Table 18. Factors Affecting Fetal Heart Rate

<table>
<thead>

Fetal Factors
- Arrhythmia, anemia, infection, prolonged activity, chronic hypoxemia, congenital anomalies
- Rapid descent, dysrhythmia, heart block, hypoxia, vaginal stimulation (head compression), hypothermia, acidosis
- CNS anomalies
- Dyshytmia
- Inactivity/sleep cycle, preterm fetus

Drugs
- β-blockers
- Anesthetics
- Narcotics, sedatives
- Magnesium sulphate, β-blockers

Uteroplacental
- Early hypoxia (abruption, HTN)
- Late hypoxia (abruption, HTN)
- Acute cord prolapse
- Hypercontractility
- Hypoxia

Table 19. Comparison of Decelerations

Early Decelerations
- Uniform shape with onset early in contraction, returns to baseline by end of contraction, mirrors contraction (nadir occurs at peak of contraction)
- Gradual deceleration and return to baseline
- Often repetitive; no effect on baseline FHR or variability
- Benign, due to vagal response to head compression

Variable Decelerations
- Variable in shape, onset, and duration
- Most common type of periodicity seen during labour
- Often with abrupt drop in FHR >15 bpm below baseline (>15 s, <2 min); usually no effect on baseline FHR or variability
- Due to cord compression or, in second stage, forceful pushing with contractions

Complicated Variable Decelerations
- FHR drop <70 bpm for >60 s
- Loss of variability or decrease in baseline after deceleration
- Biphasic deceleration
- Slow return to baseline
- Baseline tachycardia or bradycardia
- May be associated with fetal academia

Late Decelerations
- Uniform shape with onset, nadir, and recovery occurring after peak of contraction, slow return to baseline
- May cause decreased variability and change in baseline FHR
- Due to fetal hypoxia and acidemia, maternal hypotension, or uterine hypertonus
- Usually a sign of uteroplacental insufficiency (an ominous sign)

</table>

| Accelerations                   | Accelerations spontaneous or during scalp stimulation | Absent with scalp stimulation | Nearly absent |

| Action                          | EFM may be interrupted for \(\leq 30\) min if mother/fetus stable | Further assessment required | Action required: review clinical situation, obtain scalp pH, prepare for possible delivery |

Adapted from SOGC Guidelines, September 2008

*Previous classification was “reassuring” vs. “non-reassuring”, but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) versus those with major concerns requiring immediate intervention (abnormal)

Fetal Oxygenation
- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
- fetal response to hypoxia/asphyxia:
  - decreased movement, tone, and breathing activities
  - anaerobic metabolism (decreased pH)
  - transient fetal bradycardia followed by fetal tachycardia
  - redistribution of fetal blood flow
    - increased flow to brain, heart, and adrenals
    - decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
    - increase in blood pressure

### Induction of Labour

**Definition**
- artificial initiation of labour in a pregnant woman prior to spontaneous initiation to deliver the fetus and placenta

**Prerequisites for Labour Induction**
- capability for C/S if necessary
- maternal
  - short, thin, soft, anterior cervix with open os (“inducible” or “ripe”)
  - if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prevadin®), or Foley catheter
- fetal
  - normal fetal heart tracing
  - cephalic presentation
  - adequate fetal monitoring available

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labour and delivery
• likelihood of success determined by Bishop score
  ▪ cervix considered unfavourable if <6
  ▪ cervix favourable if ≥6
  ▪ score of 9-13 associated with high likelihood of vaginal delivery

**Table 22. Bishop Score**

**Indications**

- post-dates pregnancy (generally >41 wk) = most common reason for induction
- maternal factors
  ▪ DM = second most common reason for induction
  ▪ gestational HTN
  ▪ other maternal medical problems, e.g. renal or lung disease, chronic hypertension, cholestasis or pregnancy
  ▪ maternal age over 40
- maternal-fetal factors
  ▪ isoimmunization, PROM, chorioamnionitis, post-term pregnancy
- fetal factors
  ▪ suspected fetal jeopardy as evidenced by biochemical or biophysical indications
  ▪ fetal demise. IUGR, oligo/polyhydraminos, anomalies requiring surgical intervention, twins
  ▪ previous still birth, low PAPP-A

**Risks**

- failure to achieve labour and/or vaginal birth
- uterine hyperstimulation with fetal compromise or uterine rupture
- maternal side effects to medications
- uterine atony and PPH

**Contraindications**

- maternal
  ▪ prior classical or inverted T-incision C/S or uterine surgery (e.g. myomectomy)
  ▪ unstable maternal condition
  ▪ active maternal genital herpes
  ▪ invasive cervical carcinoma
  ▪ pelvic structure deformities
- maternal-fetal
  ▪ placenta previa or vasa previa
  ▪ cord presentation
- fetal
  ▪ fetal distress, malpresentation /abnormal lie, preterm fetus without lung maturity

**Induction Methods**

**CERVICAL RIPENING**

**Definition**

- use of medications or other means to soften, efface, and dilate the cervix, increases likelihood of successful induction
- ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

**Methods**

- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  ▪ recommended dosing interval of prostaglandin gel is every 6 to 12 h up to 3 doses
- intravaginal PGE2 (Cervidil®): long and closed cervix, may use if ROM
  ▪ continuous release, can be removed if needed
  ▪ controlled release PGE2
- Foley catheter placement to mechanically dilate the cervix
INDUCTION OF LABOUR

Amniotomy
• artificial rupture of membranes (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is open and soft, the membranes can be felt, and if the head is present at the cervix
• few studies address the value of amniotomy alone for induction of labour
• amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

Oxytocin
• oxytocin (Pitocin®): 10 U in 1L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min
  ▪ reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
  ▪ ideal dosing regime of oxytocin is not known
  ▪ current recommendations: use the minimum dose to achieve active labour and increase q30min as needed
  ▪ reassessment should occur once a dose of 20 mU/min is reached
• potential complications
  ▪ hyperstimulation/tetanic contraction (may cause fetal distress or rupture of uterus)
  ▪ uterine muscle fatigue, uterine atony (may result in PPH)
  ▪ vasopressin-like action causing anti-diuresis

Augmentation of Labour
• augmentation of labour is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur
• oxytocin (0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min)

Abnormalities and Complications of Labour and Delivery

Meconium in Amniotic Fluid

Epidemiology
• present early in labour in 10% of pregnancies
• in general, meconium may be present in up to 25% of all labours; usually NOT associated with poor outcome, but extra care is required at time of delivery to avoid aspiration. Concern is fluid changes from clear to meconium stained. Always abnormal if seen in preterm patient

Etiology
• likely cord compression ± uterine hypertonia
• may indicate undiagnosed breech
• increasing meconium during labour may be a sign of fetal distress

Features
• may be watery or thicker
• light yellow/green or dark green-black in colour

Treatment
• call respiratory therapy, neonatology, or pediatrics to delivery room
• oropharynx suctioning upon head expulsion or immediately after delivery if baby not breathing spontaneously (do NOT stimulate infant before)
• consider amnioinfusion of ~800 mL of IV NS over 50-80 min during active stage of labour and a maintenance dose of ~3 mL/min until delivery
• closely monitor FHR for signs of fetal distress
Abnormal Progression of Labour (Dystocia)

**Definition**
- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour
- during active phase: >4 h of <0.5 cm/h
- during 2nd phase: >1 h with no descent during active pushing

**Etiology**
- **Power** (leading cause): contractions (hypotonic, incoordinate), inadequate maternal expulsive efforts
- **Passenger**: fetal position, attitude, size, anomalies (hydrocephalus)
- **Passage**: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- **Psyche**: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

**Management**
- confirm diagnosis of labour (rule out false labour)
- search for factors of CPD
- diagnosed if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
- management: if CPD ruled out, IV oxytocin augmentation ± amniotomy

**Risks of Dystocia**
- inadequate progression of labour is associated with an increased incidence of:
  - maternal stress
  - maternal infection
  - postpartum hemorrhage
  - need for neonatal resuscitation
  - fetal compromise (from uterine hyperstimulation)
  - uterine rupture
  - hypotension

Shoulder Dystocia

**Definition**
- fetal anterior shoulder impacted above symphysis pubis after fetal head has been delivered
- life threatening emergency

**Etiology/Epidemiology**
- incidence 0.15-1.4% of deliveries
- occurs when breadth of shoulders is greater than biparietal diameter of the head

**Risk Factors**
- maternal: obesity, DM, multiparity, previous shoulder dystocia
- fetal: prolonged gestation, macrosomia
- labour
  - prolonged 2nd stage
  - instrumental midpelvic delivery

**Clinical Features**
- "turtle sign": head delivered but retracts against inferior portion of pubic symphysis
- complications
  - fetal:
    - hypoxic ischemic encephalopathy (chest compression by vagina or cord compression by pelvis can lead to hypoxia)
    - brachial plexus injury (Erb’s palsy: C5-C7; Klumpke’s palsy: C8-T1), 90% resolve within 6 mo
    - fracture (clavicle, humerus, cervical spine)
    - death
  - maternal:
    - perineal injury
    - PPH (uterine atony, lacerations)
    - uterine rupture

**Treatment**
- goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved
• other options
  - cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
  - symphysiotomy

Prognosis
• 1% risk of long-term disability for infant

### Umbilical Cord Prolapse

**Definition**
• descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

**Etiology/Epidemiology**
• increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, CPD
• incidence: 1/200 – 1/400 deliveries

**Clinical Features**
• visible or palpable cord
• FHR changes (variable decelerations, bradycardia, or both)

**Treatment**
• emergency C/S
• O2 to mother, monitor fetal heart
• alleviate pressure of the presenting part on the cord by placing digit in vagina (maintain this position until C/S)
• keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
• roll mom onto all fours
• position mother in Trendelenburg or knee-to-chest position
• if fetal demise or too premature (<22 wk), allow labour and delivery

### Uterine Rupture

**Etiology/Epidemiology**
• associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity, and previous intrauterine manipulation
• generally occurs during labour, but can occur earlier with a classical incision
• 0.5-0.8% incidence, up to 12% with classical incision

**Clinical Features**
• prolonged fetal bradycardia – most common presentation
• acute onset of constant lower abdominal pain, may not have pain if receiving epidural analgesia
• hyper or hypotonic uterine contractions
• vaginal bleeding
• intra-abdominal hemorrhage

**Risk Factors**
• uterine scarring (i.e. previous uterine surgeries including Cesarean, perforation with D&C, myomectomy)
• excessive uterine stimulation (i.e. protracted labour, oxytocin, prostaglandins)
• uterine trauma (i.e. operative equipment, ECV)
• multiparity
• uterine abnormalities
• placenta accreta

**Treatment**
• rule out placental abruption
• immediate delivery for fetal survival
• maternal stabilization (may require hysterectomy), treat hypovolemia

**Complications**
• maternal mortality 1-10%
• maternal hemorrhage, shock, DIC
• amniotic fluid embolus
• hysterectomy if uncontrollable hemorrhage
• fetal distress, associated with 50% fetal mortality

*In Canada (2013), lifetime risk of maternal death is 1 in 5,200
Amniotic Fluid Embolus

**Definition**
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

**Etiology/Epidemiology**
- rare intrapartum or immediate postpartum complication
- 60-80% maternal mortality rate, accounts for 10% of all maternal deaths
- leading cause of maternal death in induced abortions and miscarriages
- 1/8,000-1/80,000 births

**Risk Factors**
- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation

**Differential Diagnosis**
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, chronic coagulopathy

**Clinical Features**
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

**Management**
- supportive measures (high flow O₂, ventilation support, fluid resuscitation, inotropic support, ± intubation), coagulopathy correction
- ICU admission

Chorioamnionitis

**Definition**
- infection of the chorion, amnion, and amniotic fluid typically due to ascending infection by organisms of normal vaginal flora

**Etiology/Epidemiology**
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending from vagina
- predominant microorganisms include: GBS, *Bacteroides* and *Prevotella* species, *E. coli*, and anaerobic *Streptococcus*

**Risk Factors**
- prolonged ROM, long labour, multiple vaginal exams during labour, internal monitoring
- bacterial vaginosis and other vaginal infections

**Clinical Features**
- maternal fever, maternal or fetal tachycardia, uterine tenderness, foul, and purulent cervical discharge

**Investigations**
- CBC: leukocytosis
- amniotic fluid: leukocytes or bacteria

**Treatment**
- IV antibiotics
  - ampicillin (2 g IV q6h) and gentamicin (1.5 mg/kg q8h)
  - anaerobic coverage (i.e. clindamycin if C/S)
- expedient delivery regardless of gestational age

**Complications**
- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, infant meningitis
Operative Obstetrics

Operative Vaginal Delivery

Definition
• forceps or vacuum extraction

Indications
• fetal
  ▪ atypical or abnormal fetal heart rate tracing, evidence of fetal compromise
  ▪ consider if second stage is prolonged as this may be due to poor contractions or failure of fetal head to rotate
• maternal
  ▪ need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  ▪ exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

Contraindications
• non-cephalic presentation
• unengaged head
• cervix incompletely dilated

Forceps

Outlet Forceps Position
• head visible between labia in between contractions
• sagittal suture in or close to AP diameter
• rotation cannot exceed 45°

Low Forceps Position
• presenting part at station +2 or greater
• subdivided based on whether rotation less than or greater than 45 degrees

Mid Forceps Position
• presenting part below spines but above station +2

Types of Forceps
• Simpson or Tucker-McLane forceps for OA presentations
• Kielland (rotational) forceps when rotation of head is required
• Piper forceps for breech

Vacuum Extraction
• traction instrument used as alternative to forceps delivery; aids maternal pushing
• contraindications: <34 wk GA, fetal head deflexed, fetus requires rotation, fetal condition (e.g. bleeding disorder)

Table 23. Advantages and Disadvantages of Forceps versus Vacuum Extraction

Limit for Trial of Vacuum
• After 3 pulls over 3 contractions with no progress
• After 3 pop-offs with no obvious cause
• 20 min and delivery is not imminent
Lacerations
- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter but does not extend through it
- fourth degree: extends through the anal sphincter into the rectal mucosa

Episiotomy
Definition
- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernous muscle
  - heals better, but increases risk of 3\(\frac{3}{4}\)th degree tears
- mediolateral: incision through bulbocavernous, superficial transverse perineal muscle, and levator ani
  - reduced risk of extensive tear but more painful
  - easier to repair

Indications
- to relieve obstruction of the unyielding perineum
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

Complications
- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, incontinence

Cesarean Delivery
Epidemiology
- incidence 20-25%

Indications
- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery (past C/S is most common), underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies

Types of Cesarean Incisions
- skin
  - transverse (i.e. Pfannensteil)
  - decreased exposure and slower entry
  - improved strength and cosmesis
- vertical midline
  - rapid peritoneal entry and increased exposure
  - increased dehiscence
- uterine
  - low transverse (most common): in noncontractile segment
  - decreased chance for rupture in subsequent pregnancies
- low vertical
  - used for very preterm infants, poorly developed maternal lower uterine segment
  - classical (rare): in thick, contractile segment
  - used for transverse lie, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, morbidly obese patients

Risks/Complications
- anesthesia
- hemorrhage (average blood loss ~1,000 cc)
- infection (UTI, wound, endometritis)
  - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- injury to surrounding structures (bowel, bladder, ureter, uterus)
- thromboembolism (DVT, PE)
- increased recovery time/hospital stay
- maternal mortality (<0.1%)

Muscles of Perineal Body
- Superficial transverse perineal
- Bulbocavernous
- External anal sphincter

Risk Factors for Primary and Subsequent Anal Sphincter Lacerations
Am J Obstet Gynecol 2007;196:344
Objective: Assess effects of pregnancy, delivery, and parity on risk of primary and secondary anal sphincter laceration in women with 1st vaginal delivery (VD), VBAC, or 2nd VD.
Methods: Retrospective cohort study of all deliveries at one hospital from 1995-2002.
Conclusion: 20,074 live singleton deliveries were included. Women with first VD and VBAC both had OR 5.1 for laceration compared to 2nd VD. Forceps and midline episiotomy significantly increased risk of laceration for all 3 groups. Second stage of labor >2 h only increased risk for 1st VD. Factors that had no significant increase in risk: infant birth weight >3,500 g and vacuum delivery. Women with prior anal sphincter laceration are at 3x increased risk for subsequent sphincter laceration, compared with women with prior vaginal delivery without sphincter laceration.

Restrictive vs. Routine Episiotomies with Vaginal Births
Cochrane DB Syst Rev 2009;1:CD000081
Study: This systematic review and meta-analysis of 8 RCTs assessed the effects of restrictive (only done for fetal indications or if severe perineal trauma was judged to be imminent) and routine (liberally done to prevent any tear) use of episiotomy during vaginal birth.
Patients: Of the 2,709 patients in the routine episiotomy group, 2,035 (75%) women had episiotomies. In the restrictive episiotomy group, 776 (28%) of the 2,733 women had episiotomies. The restrictive episiotomy group, 776 (28%) of the 2,733 women had episiotomies.
Results: Restrictive episiotomies appear to have less severe perineal trauma (RR 0.67), less suturing (RR 0.71), and fewer healing complications at 7 d (RR 0.69) compared to routine episiotomies. There is no difference for pain measures, dyspareunia, urinary incontinence, and severe vaginal or perineal trauma, but there was an increased risk of anterior perineal trauma (RR 1.84) with restrictive episiotomy. Similar results were obtained when comparing restrictive versus routine mediolateral versus midline episiotomy.
Conclusions: Compared to routine use, restrictive use of episiotomy during vaginal delivery appears to be more beneficial.

Common OR Questions
7 Layers to Dissect
Skin, fatty layer, fascia, muscle separation (rectus abdominis), peritoneum, bladder flap, uterus

Layers of the Rectus Sheath
Above the arcuate line: external oblique, internal oblique, rectus abdominis, internal oblique, transversus abdominis
Below the arcuate line: external oblique, internal oblique, transversus abdominis, rectus abdominis

Name of the Obliterated Umbilical Ligament
Urachus
Vaginal Birth After Cesarean (Trial of Labour After Cesarean)

- recommended after previous low transverse incision
- success rate varies with indication for previous C/S (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision)

Contraindications
- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- history of uterine surgery (e.g. myomectomy) or previous uterine rupture
- multiple gestation
- non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency C/S

Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

Postpartum Hemorrhage

Definition
- loss of >500 mL of blood at the time of vaginal delivery, or >1,000 mL with C/S
- early (immediate) – within first 24 h postpartum
- late (delayed) – after 24 h but within first 6 wk

Epidemiology
- incidence 5-15%

Etiology (4 Ts)
1. Tone
   - uterine atony
     - most common cause of PPH
     - avoid by giving oxytocin with delivery of the anterior shoulder or placenta
     - occurs within first 24 h
   - due to
     - overdistended uterus (polyhydramnios, multiple gestations, macrosomia)
     - uterine muscle exhaustion (prolonged or rapid labour, grand multiparity, oxytocin use, general anaesthetic)
     - uterine distortion (fibroids, placenta previa, placental abruption)
     - intra-amniotic infection (fever, prolonged ROM)

2. Tissue
   - retained placental products (membranes, cotyledon or succenturiate lobe)
   - retained blood clots in an atonic uterus
   - gestational trophoblastic neoplasia
   - abnormal placentation

3. Trauma
   - laceration (vagina, cervix, uterus), episiotomy, hematoma (vaginal, vulvar, retroperitoneal), uterine rupture, uterine inversion

4. Thrombin
   - coagulopathy (pre-existing or acquired)
     - most identified prior to delivery (low platelets increases risk)
     - includes hemophilia, DIC, Aspirin use, ITP, TTP, vWD (most common)
     - therapeutic anti-coagulation

Investigations
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of tone, tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

Management
- ABCs, call for help
- 2 large bore IVs, run crystalloids wide open
- CBC, coagulation profile, cross and type 4 units pRBCs
- treat underlying cause
- Foley catheter to empty bladder and monitor urine output

Uterine atony is the most common cause of PPH

DDx of Early PPH – 4 Ts
- Tone (atony)
- Tissue (retained placenta, clots)
- Trauma (laceration, inversion)
- Thrombin (coagulopathy)

DDx of Late PPH
- Retained products ± endometritis
- Sub-involution of uterus
Medical Therapy
- oxytocin 5U IV bolus with delivery of anterior shoulder
  - 20–40 U/250 mL in crystalloid
  - in addition can give 10 U IM if CV collapse or IV access not possible
- methylergonovine maleate (ergotamine) 0.25 mg IM/IMM q5min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carboprost (Hemabate®), a synthetic PGF-1α analog 250 µg IM/IMM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600–800 µg po/sl (faster) or pr/pv (side effect: pyrexia if >600 µg)
- tranexamic acid (Cyklokapron®) 1 g IV, an antifibrinolytic

Local Control
- bimanual compression: elevate the uterus and massage through patient’s abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

Surgical Therapy (Intractable PPH)
- D&C (beware of vigorous scraping which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), internal iliac artery (not proven), ovarian artery, or hypogastric artery
- hysterectomy last option with angiographic embolization if post-hysterectomy bleeding

Retained Placenta

Definition
- placenta undelivered after 30 min postpartum

Etiology
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, placenta percreta)

Risk Factors
- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, uterine infection

Clinical Features
- risk of postpartum hemorrhage and infection

Investigations
- explore uterus
- assess degree of blood loss

Management
- 2 large bore IVs, type and screen
- Brant maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required

Uterine Inversion

Definition
- inversion of the uterus through cervix ± vaginal introitus

Etiology/Epidemiology
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous (lax uterine ligaments)
- 1/1,500–1/2,000 deliveries

Clinical Features
- can cause profound vasovagal response with bradycardia, vasodilation, and hypovolemic shock
- shock may be disproportionate to maternal blood loss
Management
• urgent management essential, call anesthesia
• ABCs: initiate IV crystalloids
• can use tocolytic drug (see ‘Management’ of Preterm Labour, OB16) or nitroglycerin IV to relax uterus and aid replacement
• replace uterus without removing placenta
• remove placenta manually and withdraw slowly
• IV oxytocin infusion (only after uterus replaced)
• re-explore uterus
• may require general anesthetic ± laparotomy

Postpartum Pyrexia

Definition
• fever >38°C on any 2 of the first 10 d postpartum, except the first day

Etiology
• endometritis
• wound infection (check C/S and episiotomy sites)
• mastitis/engorgement
• UTI
• atelectasis
• pneumonia
• DVT, pelvic thrombophlebitis

Investigations
• detailed history and physical exam, relevant cultures
• for endometritis: blood and genital cultures

Treatment
• depends on etiology
  ▪ infection: empiric antibiotics, adjust when sensitivities available
    • endometritis: clindamycin + gentamycin IV
    • mastitis: cloxacillin or cephalaxin
    • wound infection: cephalaxin, frequent sitz baths for episiotomy site infection
  ▪ DVT: anticoagulants
• prophylaxis against post-C/S endometritis: begin antibiotic immediately after cord clamping and administer only 1-3 doses – cefazolin is most common choice

ENDOMETRITIS
• definition: infection of uterine myometrium and parametrium
• clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling discharge, or lochia
• treatment: depends on infection severity; oral antibiotics if well, IV with hospitalization in moderate to severe cases

VENOUS THROMBOEMBOLISM
• see Venous Thromboembolism, OB31

Mastitis
• definition: inflammation of mammary glands
• must rule out inflammatory carcinoma, as indicated
• differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women
Table 24. Lactational vs. Non-Lactational Mastitis

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Fever, leukocytosis</td>
<td>May develop mammary duct fistula</td>
</tr>
<tr>
<td></td>
<td>Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&amp;D usually required</td>
<td>A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually S. aureus)</td>
</tr>
</tbody>
</table>

Postpartum Mood Alterations

**POSTPARTUM BLUES**
- 40-80% of new mothers, onset day 3-10; extension of the “normal” hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency, anxiety, insomnia

**POSTPARTUM DEPRESSION**
- definition: major depression occurring in a woman within 6 mo of childbirth (see Psychiatry, PS12)
- epidemiology: 10-15%, risk of recurrence 50%
- risk factors
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- clinical features: suspect if the “blues” last beyond 2 wk, or if the symptoms in the first 2 wk are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
- assessment: Edinburgh Postnatal Depression Scale or other
- treatment: antidepressants, psychotherapy, supportive care, ECT if refractory
- prognosis: interferes with bonding and attachment between mother and baby so it can have long-term effects

**POSTPARTUM PSYCHOsis**
- definition: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- epidemiology: rare (0.2%)
Postpartum Care

Postpartum Office Visit at 6 Weeks

Care of Mother (The 10 Bs)
- Be careful: do not use douches or tampons for 4-6 wk post-delivery
- Be fit: encourage gradual increases in walking, Kegel exercises
- Birth control: assess for use of contraceptives; breastfeeding is NOT an effective method of birth control (see Gynecology, GY18, for more detail about different contraceptive options postpartum)
- Bladder: assess for urinary incontinence, maintain high fluid intake
- Blood pressure: especially if gestational HTN
- Blood tests: glucose, CBC (for anemia as sign of hematomas, retained placenta)
- Blues: (see Postpartum Mood Alterations)
- Bowel: fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, Sitz baths, ice compresses
- Breast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk

Physiological Changes Postpartum
- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d for non-lactating women and within 3-6 mo for lactating women
- lochia: normal vaginal discharge postpartum, uterine decidual tissue sloughing
  - decreases and changes in colour from red (lochia rubra; presence of erythrocytes, 3-4 d) → pale (lochia serosa) → white / yellow (lochia alba; residual leukorrhea) over 3-6 wk
  - foul-smelling lochia suggests endometritis

Breastfeeding Problems
- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisture cream, topical steroid if needed
- mastitis: treat promptly (see Postpartum Pyrexia, OB47)
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see Breastfeeding and Drugs)

Bladder Dysfunction
- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management: pelvic floor retraining with Kegel exercises, vaginal cone, or pessaries, lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management: minimally invasive procedures (tension-free vaginal tape, transobturator tape, midurethral sling)

Puerperal Pain
- “after pains” common in 1st 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

Breastfeeding and Drugs

Table 25. Drug Safety During Breastfeeding

<table>
<thead>
<tr>
<th>Safe During Breastfeeding</th>

Breastfeeding: Contraindicated Drugs

BREAST
- Bromocriptine/Benzodiazepines
- Radioactive isotopes/Rizatriptan
- Ergotamine/Ethosuximide
- Amiodarone/Amphetamines
- Stimulant laxatives/Sex hormones
- Tetracycline/Tretinoin
## Table 26. Common Medications

<table>
<thead>
<tr>
<th>Drug Name (Brand Name)</th>
<th>Dosing Schedule</th>
<th>Indications/Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>betamethasone valerate (Celestone®)</td>
<td>12 mg IM q24h x 2 doses</td>
<td>Enhancement of fetal pulmonary maturity for PTL</td>
</tr>
<tr>
<td>carboprost (Hemabate®)</td>
<td>0.25 mg IM/MM q15min; max 2 mg</td>
<td>Treatment of uterine atony</td>
</tr>
<tr>
<td>cefazolin</td>
<td>2 g IV then 1 g q8h</td>
<td>GBS prophylaxis (penicillin allergic and not at risk for anaphylaxis)</td>
</tr>
<tr>
<td>clindamycin</td>
<td>900 mg IV q8h</td>
<td>Used in endometritis</td>
</tr>
<tr>
<td>dexamethasone</td>
<td>6 mg IM q12h x 4 doses</td>
<td>Enhancement of fetal pulmonary maturity for PTL</td>
</tr>
<tr>
<td>dinoprostone (Cervidil®: PGE2 impregnated thread)</td>
<td>10 mg PV (remove after 12 h) max 3 doses</td>
<td>Induction of labour Advantage: can remove if uterine hyperstimulation</td>
</tr>
<tr>
<td>doxylamine succinate (Diclectin®)</td>
<td>2 tabs qhs + 1 tab qAM + 1 tab qPM max 8 tabs/d</td>
<td>Each tablet contains 10 mg doxylamine succinate with vitamin B6 Used for hyperemesis gravidarum</td>
</tr>
<tr>
<td>erythromycin</td>
<td>500 mg IV q6h</td>
<td>GBS prophylaxis (penicillin allergic and at risk for anaphylaxis)</td>
</tr>
<tr>
<td>folic acid</td>
<td>0.4-1 mg PO OD x 1-3 mo preconception and T1 5 mg PO OD with past Hx of NTD</td>
<td>Prevention of oNTD</td>
</tr>
<tr>
<td>methotrexate</td>
<td>50 mg/m² IM or 50 mg PO x 1 dose</td>
<td>For ectopic pregnancy or medical abortion</td>
</tr>
<tr>
<td>methylergonovine maleate (Ergotamine®)</td>
<td>0.25 mg IM/MM q5min up to 1.25 mg or IV bolus 0.125 mg</td>
<td>Treatment of uterine atony</td>
</tr>
<tr>
<td>misoprostol (Cytotec®)</td>
<td>600-1000 µg P9 x 1 dose 400 µg PO/SL x 1 dose or 800 µg PV x 1 dose, 3-7 d after methotrexate</td>
<td>For treatment of PPH For medical abortion/retained products of conception Also used for NSAID-induced ulcers (warn patients of contraindications)</td>
</tr>
<tr>
<td>oxytocin (Pitocin®)</td>
<td>0.5-2.0 mL/min IV, or 10 U/L NS increase by 1-2 mL/min q20-60min max 36-48 mL/min 10 U IM at delivery of anterior shoulder and of placenta 20 U/L NS or RL IV continuous infusion</td>
<td>Augmentation of labour (also induction of labour) Prevention of uterine atony Treatment of uterine atony</td>
</tr>
<tr>
<td>Penicillin G</td>
<td>5 million U IV then 2.5 million U IV q4h until delivery</td>
<td>GBS prophylaxis</td>
</tr>
<tr>
<td>PGE2 gel (Prostin® gel)</td>
<td>0.5 mg PV q6-12h; max 3 doses</td>
<td>Induction of labour</td>
</tr>
<tr>
<td>Rh IgG (Rhogam®)</td>
<td>300 µg IM x 1 dose</td>
<td>Given to Rh negative women • Routinely at 28 wk GA • Within 72 h of birth of Rh+ fetus • Positive Kleihauer-Betke test • With any invasive procedure in pregnancy • Ectopic pregnancy • Antepartum hemorrhage • Miscarriage or therapeutic abortion (dose: 50 µg IM only)</td>
</tr>
</tbody>
</table>

Common Discharge Medications

- Oxycodone IR 5-10 mg PO q4-6h PRN
- Docusate sodium 100 mg PO bid

Misoprostol (Cytotec®) is also indicated to protect against NSAID-induced gastric ulcers in non-pregnant individuals. The use of misoprostol for cytoprotection is contraindicated in pregnancy; warn female patients of this contraindication.

## Basic Anatomy Review

### Figure 1. Anatomy of the eye

![Diagram of the eye](https://example.com/diagram.png)

- **Tendon of superior rectus muscle**
- **Ciliary muscle and body**
- **Conjunctival fornix**
- **Lens**
- **Cornea**
- **Palpebral conjunctiva**
- **Bulbar conjunctiva**
- **Meibomian gland**
- **Eyelash**

### Figure 2. Layers of the retina

![Diagram of the retina](https://example.com/diagram.png)

**Retinal Layers (10):**

1. Inner limiting membrane
2. Nerve fibre layer
3. Ganglion cell layer
4. Inner plexiform layer
5. Inner nuclear layer
6. Outer plexiform layer
7. Outer nuclear layer
8. Outer limiting membrane
9. Photoreceptor layer
10. Retinal pigmented epithelium

**CELL TYPES:**

- Amacrine cells
- Bipolar cells
- Horizontal cells
- Ganglion cells
- Rod nuclei
- Cone nuclei
- Rod cells
- Cone cells
- Pigmented cells
- Bruch’s membrane
- choroid

**Light Rays:**

- Vitreous humour
- Optic nerve fibres

© Jenn Tse 2006, after Sarah A. Kim 2005
Differential Diagnoses of Common Presentations

Loss of Vision

**Transient (seconds to hours)**
- Transient ischemic attack (TIA)
- Migraine with aura
- Cornea/Anterior Segment
  - Corneal edema
  - Hyphema
  - Acute angle-closure glaucoma
  - Trauma/foreign body

**Acute (seconds to days)**
- Vitreous/Retina/Optic Nerve
  - Vitreous hemorrhage
  - RD
  - Retinal artery/vein occlusion
  - Acute macular lesion
  - Optic neuritis
  - Temporal arteritis
  - Anterior ischemic optic neuropathy (AION)
- Cortical/Other
  - Occipital infarction/hemorrhage
  - Cortical blindness
  - Functional (non-organic, diagnosis of exclusion)

**Chronic (weeks to months)**
- Cornea/Anterior Segment
  - Corneal dystrophy/scarring/edema
  - Refractive error
  - Cataract
  - Glaucoma
- Vitreous/Retina/Optic Nerve
  - AMD
  - DR
  - Retinal vascular insufficiency
  - Compressive optic neuropathy (intracranial mass, orbital mass)
  - Intraocular neoplasm
  - Retinitis pigmentosa
- Cortical/Other
  - Pituitary adenoma
  - Medication-induced (sildenafil, amiodarone)
  - Nutritional deficiency
  - Papilledema

**Top 3 Differential Diagnosis of Acute Loss of Vision**
- Vitreous hemorrhage
- Retinal artery/vein occlusion
- RD

**Top 3 Differential Diagnosis of Chronic Loss of Vision**
- Reversible
  - Cataract
  - Refractive error
  - Corneal dystrophy
- Irreversible
  - AMD
  - Glaucoma
  - DR

Note: Anti-VEGF treatment for exudative AMD and diabetic macular edema may reverse some vision loss.

Figure 3. Tear drainage from the eye (lacrimal apparatus)

Figure 4. Loss of vision
Red Eye
- lids/orbit/lacrimal system
  - hordeolum/chalazion
  - blepharitis
  - entropion/ectropion
  - foreign body/laceration
  - dacryocystitis/dacryoadenitis
- conjunctiva/sclera
  - subconjunctival hemorrhage
  - conjunctivitis
  - dry eyes
  - pterygium
  - episcleritis/scleritis
  - preseptal/orbital cellulitis
- cornea
  - foreign body (including contact lens)
  - keratitis
  - abrasion, laceration
  - ulcer
- anterior chamber
  - anterior uveitis (iritis, iridocyclitis)
  - acute glaucoma
  - hyphema (blood in anterior chamber)
  - hypopyon (pus in anterior chamber)
other
  - trauma
  - post-operative
  - endophthalmitis
  - pharmacologic (e.g. prostaglandin analogs)

Ocular Pain
- differentiate from eye fatigue (asthenopia)
- ocular surface disease
- herpes zoster prodrome
- trauma_foreign body
- blepharitis
- keratitis
- corneal abrasion, corneal ulcer
- acute glaucoma
- acute uveitis
- scleritis (rarely episcleritis)
- optic neuritis

Photophobia (Severe Light Sensitivity)
- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis, encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

Diplopia (Double Vision)
- binocular diplopia (occurs with both eyes open, eliminated with occlusion of either eye)
  - strabismus
  - CN palsy (III, IV, VI)
    - ischemia (DM)
    - tumour
    - trauma
  - myasthenia gravis
  - muscle restriction/entrapment
  - thyroid ophthalmopathy
  - INO
    - multiple sclerosis
    - brainstem infarct
- monocular diplopia (occurs with one eye open, remains with occlusion of unaffected eye)
  - refractive error
  - strands of mucus in tear film
  - keratoconus
  - cataracts
  - dislocated lens
  - peripheral laser iridotomy

Ocular Problems in the Contact Lens Wearer
- SPK from dry eyes
- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- limbal stem cell deficiency
- corneal neovascularization
- sterile corneal infiltrates (immunologic)
- infected ulcers (Pseudomonas, Acanthamoeba)

Floaters
- PVD (often secondary to age-related vitreous syneresis)
- vitreous hemorrhage
- retinal tear detachment
- intermediate uveitis (pars planitis)
- posterior uveitis (chorioretinitis)

Acute Painless Vision Loss
- vitreous hemorrhage
- retinal artery/vein occlusion
- RD
- AION
- optic neuritis
- amaurosis fugax/TIA/stroke

Flashes of Light (Photopsia)
- PVD (often secondary to age-related vitreous syneresis)
- retinal tear detachment
- migraine with aura

Ocular Emergencies

These require urgent consultation to an ophthalmologist for management

**Sight Threatening**
- lid/globe lacerations
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis
- GCA

**Life Threatening**
- proptosis (rule out cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or externally compressive neoplastic lesion)
- papilledema (elevated increased intracranial pressure work up)
- orbital cellulitis
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma)

The Ocular Examination

**Visual Acuity – Distance**
- Snellen Acuity (Figure 5) = smallest line patient can read on the chart
- e.g. 20/40 = what the patient can see at 20 feet (numerator), what a “normal” person can see at 40 feet (denominator)
- distance visual acuity should be tested with distance glasses on in order to obtain best corrected visual acuity
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)
- legal blindness is BCVA that is ≤20/200 in best eye
- minimum visual requirements to operate a non-commercial automobile in Ontario are: 20/50 BCVA with both eyes open and examined together, 120° continuous horizontal visual field, and 15° continuous visual field above and below fixation

Not every red eye has conjunctivitis
Visual Acuity – Near
- use pocket visual chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance VA possible (e.g. immobile patient, no distance chart available)

Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics
- newborns
  - VA cannot be tested
- 3 mo-3 yr (can only assess visual function, not acuity)
  - test each eye for fixation symmetry using an interesting object
  - normal function noted as “CSM” = central, steady, and maintained
- 3 yr until alphabet known
  - pictures or letter cards/charts such as HOTV or Sheridan-Gardner test (children point to optotypes on a provided matching card)
  - tumbling “E” chart

Colour Vision
- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye, specify incorrect plates
- important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
- note: red-green colour blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS
- test “visual fields by confrontation” (4 quadrants, each eye tested separately) for estimation of visual field loss
- accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- use Amsler grid (each eye tested separately) to check for central or paracentral scotomas (island-like gaps in the vision) in patients with AMD

PUPILS
- use reduced room illumination with patient focusing on distant fixed object to prevent “near reflex”
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- test for RAPD with swinging flashlight test, check by reverse RAPD if one pupil non-reactive
- test pupillary constriction portion of near reflex by bringing object close to patient’s nose
- “normal” pupil testing often noted as PERRLA (pupils equal, round, and reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH
- shine light tangentially from temporal side
- if >2/3 of nasal side of iris in shadow → shallow anterior chamber

The van Herick Method
- shine thin-angled slit beam onto the peripheral cornea of each eye, view at a 60° angle from the beam
- estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
- ratios ≤1/4 implies risk of occludable angle; however, if >1/4 this does not rule out. Gonioscopy is gold-standard

Gonioscopy
- allows direct visualization of the angle structures using mirrored contact lens
- angle considered open if trabecular meshwork, scleral spur, and iris processes are visualized
- angle considered narrow (occludable) if only Schwalbe’s line (the termination of Descemet’s membrane) or a small portion of the trabecular meshwork is seen
- angle considered open if scleral spur seen (insertion point of ciliary body muscles)
EXTRAOCULAR MUSCLES

Alignment
- Hirschberg corneal reflex test
  - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  - shine light into patient's eyes from ~30 cm away
  - corneal light reflex should be symmetric and at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing)
  (see Strabismus, OP38)

Movement
- examine movement of eyeball through six cardinal positions of gaze
- ask patient if diplopia or pain is present in any position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal
- see sidebar for cranial nerve innervation of extraocular muscles

Diplopia
- major symptom associated with dysfunction of extraocular muscles or abnormalities of the motor nerves innervating these muscles
- must first determine whether diplopia is monocular or binocular
- determine whether diplopia was sudden onset (due to an acute event such as ischemia) or gradual (due to progressive process such as tumour or inflammation)
- with myasthenia gravis, diplopia and ptosis usually worsen on prolonged upgaze; can rule out with a 'Tensilon' test (see Neurology, N40)
- if suspect compressive lesion (most commonly seen with CN III palsy with a blown pupil), need MRI and angiography to rule out aneurysm or tumour
- new-onset diplopia that disappears with occlusion of either eye (binocular diplopia) needs urgent referral while chronic binocular diplopia and monocular diplopia should be referred non-urgently

Figure 9. Diplopia

EXTERNAL EXAMINATION
- four Ls
  - lymph nodes (preauricular, submandibular)
  - lids
  - lashes
  - lacrimal system
SLIT-LAMP EXAMINATION
- systematically examine all structures of the anterior segment and anterior vitreous (for structures see Figure 1)
- when necessary, use:
  - fluorescein dye: stains Bowman’s membrane in de-epithelialized cornea; dye appears fluorescent green with cobalt blue filtered light
  - Rose Bengal dye: stains devitalized corneal epithelium
- special lenses (78 or 90 D) used with the slit-lamp allow a binocular, stereoscopic, inverted and flipped view of the fundus and vitreous

TONOMETRY
- measurement of IOP
- normal range is 9-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by:
  - Goldmann Applanation Tonometry (GAT): clinical gold standard, performed using the slit-lamp with special tip (prism)
  - Tono-Pen®: benefit is portability and use of disposable probe tips. Use when cornea is scarred/ asymmetric (GAT inaccurate)
  - air puff (non-contact and least reliable)
- use topical anesthetic for GAT and Tono-Pen®; apply fluorescein dye when using GAT

OPHTHALMOSCOPY/FUNDOSCOPY
- performed with
  - direct ophthalmoscope (monocular with small field of view, only posterior pole visualized)
  - slit-lamp with 78 or 90 D lens (binocular view, visualization to mid-periphery of retina)
  - indirect ophthalmoscope with headlamp and 20 or 28 D lens (binocular view, visualization of entire retina to ora serrata/edge of retina)
- best performed with pupils dilated (for list of mydriatics and cycloplegics see Table 11, OP45)
  1. assess red reflex
     - light reflected off the retina produces a “red reflex” when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract, retinoblastoma)
  2. examine the posterior segment of the eye
     - vitreous
     - optic disc (colour, C:D ratio, sharpness of disc margin)
     - macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
- contraindications to pupillary dilatation
  - shallow anterior chamber – can precipitate acute angle-closure glaucoma
  - iris-supported anterior chamber lens implant
  - potential neurologic abnormality requiring pupil evaluation
  - use caution with cardiovascular abnormality – mydriatics may cause tachycardia

REFRACTION
- two techniques used
  - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
    - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
    - a typical lens prescription would contain
      - sphere power in D (measurement of refractive power of lens, equal to reciprocal of focal length in meters)
      - cylinder power in D to correct astigmatism (always positive value)
      - axis of cylinder in degrees
      - “add” (bifocal/progressive reading lens) for presbyopes
      - e.g. -1.50 + 1.00 x 120 degrees, add +2.00

REFRACTIVE EYE SURGERY
- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK (see Surgical Ophthalmology, OP44)
- potential risks/side-effects: infection, under/overcorrection, decreased night vision (nyctalopia), corneal haze, dry eyes, regression, complete sever of corneal flap (LASIK only)

**Imaging Modalities**

- **adaptive optics scanning laser ophthalmology – optical coherence tomography (SLO-OCT)**
  - combines the surface detail of confocal ophthalmoscopy with the internal detail of OCT
  - allows 3D OCT images, volume and area maps, and retinal thickness maps, at the resolution of living rods and cones
  - can visualize photoreceptors, nerve fibers and blood cells in retinal capillaries
- **CT, MRI**
  - orbital imaging, particularly in orbital trauma and neuro-ophthalmology
- **fluorescein angiography**
  - non-invasive evaluation of vascular pattern of the fundus
  - wide-field fluorescent angiogram
  - commonly used in AMD, DR, retinal vascular diseases
- **indocyanine green angiography**
  - uses infra-red light and intravenous ICG dye for imaging of choroidal structure
  - particularly useful to detect polyoidal vasculopathy (variant of AMD) more commonly present among Asian patients
• **HRT**
  ▪ confocal scanning laser tomography of retinal nerve head and surrounding nerve fiber layer
  ▪ used to assess extent of structural glaucomatous changes
• **OCT**
  ▪ non-invasive, cross-sectional, high-resolution imaging of vitreous, retinal layers, optic nerve
  ▪ commonly used to assess macular pathology/edema/holes/cysts, AMD progression, epiretinal membrane, RD
• **anterior segment optical coherence tomography (AS-OCT)**
  ▪ non-invasive, cross-sectional, high-resolution imaging of cornea, aqueous, iris, angle, and lens
• **perimetry**
  ▪ quantitative evaluation of visual fields, used to screen for scotomas and monitor progression (e.g. in glaucoma)
• **ultrasonography**
  ▪ evaluation of orbit in real-time. A-scans (one-dimensional), B-scans (two-dimensional), ultrasound biomicroscopy (UBM) (used for imaging the cornea, iris, angle) and Doppler are all used (e.g. large RDs, foreign bodies, monitoring intraocular tumours)

</table>
Treatment
• systemic antibiotics (suspect *H. influenzae* in children; *S. aureus* or *Streptococcus* in adults)
  • e.g. amoxicillin-clavulanic acid
• if severe or child <1 yr, treat as orbital cellulitis

Orbital Cellulitis
• OCULAR and MEDICAL EMERGENCY
• inflammation of orbital contents posterior to orbital septum
• common in children, elderly, and immunocompromised

Etiology
• usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

Clinical Features (see Table 4)

Treatment
• admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
• surgical drainage of abscess with close follow-up, especially in children

Complications
• optic nerve inflammation, cavernous sinus thrombosis, meningitis, and brain abscess with possible loss of vision, death

Lacrimal Apparatus
• tear film made up of three layers
  • outer oily layer (reduces evaporation): secreted by the Meibomian glands
  • middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  • inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells

• tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrimal duct → nasal cavity behind inferior concha (Figure 3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Etiology
• aqueous-deficient (lacrimal pathology)
  • Sjögren syndrome (autoimmune etiology e.g. RA, SLE)
  • non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β-blockers)
• evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  • Meibomian gland dysfunction (posterior blepharitis)
  • vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  • eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  • preserved topical ocular medications
  • contact lenses, allergic conjunctivitis
  • overlap of mixed etiologies is common

Clinical Features
• dry eyes, red eyes, foreign body sensation, blurred vision, tearing
• slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be 10 s), punctate staining of cornea with fluorescein

Investigations
• surface damage observed with fluorescein/Rose Bengal staining
• decreased distance in Schirmer’s test

Complications
• erosions and scarring of cornea

Treatment
• medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used >q1h PRN)
  • for severe cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) can be used
• procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
• treat underlying cause
Epiphora (Excessive Tearing)

Etiology
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, dacryoadenitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

Investigations
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

Treatment
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy (see Surgical Ophthalmology, OP44) – forming a new connection between the lacrimal sac and the nasal cavity

Dacryocystitis
- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with S. aureus, S. pneumoniae, Pseudomonas species

Clinical Features
- pain, swelling, redness over lacrimal sac at medial canthus
- epiphora, crusting, ± fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

Treatment
- warm compresses, nasal decongestants, systemic and topical antibiotics
- if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy (see Surgical Ophthalmology, OP44)

Dacryoadenitis
- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: S. aureus, mumps, EBV, herpes zoster, N. gonorrhoeae
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

Clinical Features
- pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

Treatment
- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

Lids and Lashes

Lid Swelling

Etiology
- commonly due to allergy, with shriveling of skin between episodes
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, thyroid disease (e.g. myxedema), trauma, chemois
Ptosis

- drooping of upper eyelid

Etiology
- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
  - incomplete opening of eyelid due to mass or scarring
- neuromuscular
  - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  - CN III palsy
  - Horner's syndrome (see Constricted Pupil, Horner's Syndrome, OP32)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)
- drugs (e.g. high dose opioids, heroin abuse, pregabalin)

Treatment
- surgery (e.g. blepharoplasty, levator resection, Müller’s muscle resection, frontalis sling)

Trichiasis

- eyelashes turned inwards
- may result from chronic inflammatory lid diseases (e.g. blepharitis), Stevens-Johnson syndrome, trauma, burns
- patient complains of red eye, foreign body sensation, significant discomfort, tearing
- may result in corneal ulceration and scarring

Treatment
- topical lubrication, eyelash plucking, electrolysis, cryotherapy

Entropion

- lid margin turns inwards towards globe causing tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause corneal abrasions with secondary corneal scarring

Etiology
- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

Treatment
- lubricants, evert lid with tape, surgery

Testing for Entropion
Forced lid closure: Ask patient to tighten lid then open. In entropion, lid rolls inwards

Ectropion

- lid margin turns outward from globe causing tearing and possibly exposure keratitis

Etiology
- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumour, herniated fat)
- congenital

Treatment
- topical lubrication, surgery

Testing for Ectropion
Snapback test: Pull eyelid inferiorly. In ectropion, lid remains away from globe

Hordeolum (Stye)

- acute inflammation of eyelid gland: either Meibomian glands (internal lid), glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)
- infectious agent is usually S. aureus
- painful, red swelling of lid

Treatment
- warm compresses, lid care, gentle massage
- topical antibiotics (e.g. erythromycin ointment bid)
- usually resolves in 2-5 d
Chalazion
- chronic granulomatous inflammation of Meibomian gland often preceded by an internal hordeolum
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, Meibomian gland carcinoma

Treatment
- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

Blepharitis
- inflammation of lid margins

Etiology
- two main types
  - staphylococcal (S. aureus): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales

Clinical Features
- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids (“toothpaste sign”)

Complications
- recurrent chalazia
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

Treatment
- warm compresses and lid scrubs with diluted “baby shampoo”
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids, omega 3 fatty acids

Xanthelasma
- eyelid xanthoma (lipid deposits in dermis of lids)
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (~50% of patients)
- common in the elderly, more concerning in the young

Treatment
- excision for cosmesis only, commonly recurs

Conjunctiva
- thin, vascular mucous membrane/epithelium
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

Pinguecula
- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea
- associated with sun and wind exposure, aging
- common, benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops
**Pterygium**

- fibrovascular, triangular, wing-like encroachment of epithelial tissue onto the cornea, usually nasally
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (5%)

**Subconjunctival Hemorrhage**

- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN, anticoagulation
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- if recurrent, consider medical/hematologic workup

**Conjunctivitis**

**Etiology**

- infectious
  - bacterial, viral, chlamydial, gonococcal, fungal, parasitic
- non-infectious
  - allergic: atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - secondary to another disorder: dacryocystitis, dacryoadenitis, cellulitis, systemic inflammatory disease

**Clinical Features**

- red eye (conjunctival injection often with limbal pallor), chemosis, subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, lid edema
- preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva, overlain by vessels
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

**ALLERGIC CONJUNCTIVITIS**

**Atopic**

- associated with rhinitis, asthma, dermatitis, hay fever
- small papillae, chemosis, thickened and erythematous lids, corneal neovascularization
- seasonal (pollen, grasses, plant allergens)
- treatment: cool compresses, antihistamine, mast cell stabilizer (e.g. ketotifen, olopatadine), topical corticosteroids

**Giant Papillary Conjunctivitis**

- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva
- treatment: clean, change or discontinue use of contact lens

**Vernal Conjunctivitis**

- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves
- treatment: consider topical steroid, topical cyclosporine (by ophthalmologist)

**VIRAL CONJUNCTIVITIS**

- serous discharge, lid edema, follicles
- subepithelial corneal infiltrates
- may be associated with rhinorrhea
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye
- mainly due to adenovirus – highly contagious for up to 12 d

**Treatment**

- cool compresses, topical lubrication
- usually self-limiting (7-12 d)
- proper hygiene is very important

**Antibiotics vs. Placebo for Acute Bacterial Conjunctivitis**

*Cochrane DB Syst Rev 2012;9:CD001211*

**Purpose:** To assess the benefits and harms of antibiotic therapy in the management of acute bacterial conjunctivitis.

**Criteria:** RCTs with any form of antibiotic treatment compared with placebo including topical, systemic or combined (e.g. antibiotics and steroids) antibiotic treatments.

**Results:** 11 RCTs, 3,673 participants. Topical antibiotics improve early (2-5 d) clinical and microbiological remission rates (RR 1.36, 95% CI 1.15-1.61; RR 1.55; 95% CI 1.37-1.76) and benefit clinical remission and microbiological cure rates at a late time point (6-10 d) (RR 1.21, 95% CI 1.10-1.32; RR 1.37, 95% CI 1.24-1.52). By 6-10 d 41% of cases had resolved in the placebo group. No serious outcomes were reported in any group.

**Conclusion:** The use of antibiotic eye drops is associated with modestly improved rates of clinical and microbiological remission in comparison to placebo. Antibiotic eye drops should therefore be considered in order to speed the resolution of symptoms and infection although acute bacterial conjunctivitis is frequently self-limiting.
BACTERIAL CONJUNCTIVITIS
• purulent discharge, lid swelling, papillae, conjunctival injection, chemosis
• common agents include *S. aureus*, *S. pneumoniae*, *H. influenzae* and *M. catarrhalis*
• in neonates or if sexually active must consider *N. gonorrhoeae* (invades cornea to cause keratitis)
• *C. trachomatis* is the most common cause in neonates

Treatment
• topical broad-spectrum antibiotic
• systemic antibiotics if indicated, especially in neonates and children
• usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

GONOCOCCAL AND CHLAMYDIAL CONJUNCTIVITIS
• caused by *N. gonorrhoea* and *C. trachomatis*, respectively
• affects sexually active individuals, neonates (ophthalmia neonatorum) in first 5 days of life when caused by gonorrhea (shorter incubation period) and days 3-14 of life when caused by chlamydia (longer incubation period)
• newborn prophylaxis with 0.5% erythromycin ointment no longer recommended
• causes trachoma and inclusion conjunctivitis (different serotypes)

Trachoma
• leading infectious cause of blindness in the world
• severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
• initially, follicles on superior palpebral conjunctiva
• treatment: topical and systemic tetracycline

Inclusion Conjunctivitis
• chronic conjunctivitis with follicles and subepithelial infiltrates
• most common cause of conjunctivitis in newborns
• newborn prophylaxis with 0.5% erythromycin ointment no longer recommended
• treatment: topical and systemic tetracycline, doxycycline, or erythromycin

Preventing Ophthalmia Neonatorum
*Paediatr Child Health* 2015;20(2):93-96
The use of silver nitrate as prophylaxis for neonatal ophthalmia was instituted in the late 1800s to prevent the devastating effects of neonatal ocular infection with *Neisseria gonorrhoeae*. At that time – during the preantibiotic era – many countries made such prophylaxis mandatory by law. Today, neonatal gonococcal ophthalmia is rare in Canada, but ocular prophylaxis for this condition remains mandatory in some provinces/territories. Silver nitrate drops are no longer available and erythromycin, the only ophthalmic antibiotic eye ointment currently available for use in newborns, is of questionable efficacy. Ocular prophylaxis is not effective in preventing chlamydial conjunctivitis. Applying medication to the eyes of newborns may result in mild eye irritation and has been perceived by some parents as interfering with mother-infant bonding. Physicians caring for newborns should advocate for rescinding mandatory ocular prophylaxis laws. More effective means of preventing ophthalmia neonatorum include screening all pregnant women for gonorrhea and chlamydia infection, and treatment and follow-up of those found to be infected. Mothers who were not screened should be tested at delivery. Infants of mothers with untreated gonococcal infection at delivery should receive ceftriaxone. Infants exposed to chlamydia at delivery should be followed closely for signs of infection.

Sclera
• white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
• continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
• episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

Episcleritis
• immunologically mediated inflammation of episclera
• 1/3 bilateral; simple (80%) or nodular (20%)
• more frequent in women than men (3:1)

Etiology
• mostly idiopathic
• in 1/3 of cases, associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, syphilis), inflammatory bowel disease, rosacea, atopy

Clinical Features
• usually asymptomatic; may have discomfort, heat sensation, red eye (often interpalpebral), rarely pain
• sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
• blanches with topical phenylephrine (constricts superficial conjunctival vessels)

Treatment
• generally self-limited, recurrent in 2/3 of cases
• topical steroid for 3-5 d if painful (prescribed and monitored by ophthalmologist)
• oral NSAID

Scleritis
• usually bilateral; diffuse, nodular, or necrotizing
• anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
• posterior scleritis: rapidly progressive blindness, may cause exudative RD
  • more common in women and elderly

Etiology
• may be a manifestation of systemic disease
• collagen vascular disease, e.g. SLE, RA, ankylosing spondylitis
• granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
• metabolic, e.g. gout, thyrotoxicosis
• infectious, e.g. S. aureus, S. pneumoniae, P. aeruginosa, herpes zoster
• chemical or physical agents, e.g. thermal, alkali, or acid burns
• idiopathic

Clinical Features
• severe pain, photophobia, red eye, decreased vision
• pain is best indicator of disease progression
• in inflammation of scleral, episcleral, and conjunctival vessels
• may have anterior chamber cells and flare, corneal infiltrate, scleral thinning, scleral edema
• sclera may have a blue hue (best seen in natural light), due to rearranged scleral fibres
• failure to blanch with topical phenylephrine

Treatment
• systemic NSAID or steroid (topical steroids are not effective)
• treat underlying etiology

Cornea

• function
  ▪ transmission of light
  ▪ refraction of light (2/3 of total refractive power of eye)
  ▪ barrier against infection, foreign bodies
• transparency due to avascularity, uniform collagen structure and deturgescence (relative dehydration)
• 6 layers (anterior to posterior): epithelium, Bowman’s membrane, stroma, Dua’s layer, Descemet’s membrane, endothelium (dehydrates the cornea; dysfunction leads to corneal edema)
• extensive sensory fibre network (V1 distribution); therefore abrasions and inflammation (keratitis) are very painful

Foreign Body
• foreign material in or on cornea
• may have associated rust ring if metallic
• patients may note tearing, photophobia, foreign body sensation, red eye
• signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, anterior chamber cells/flare

Complications
• abrasion, infection, ulcerating, rust ring, secondary iritis

Treatment
• remove under magnification using local anesthetic and sterile needle or refer to ophthalmology (depending on depth and location)
• treat as per corneal abrasion

Corneal Abrasion
• epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

Clinical Features (Table 5)
• pain, redness, tearing, photophobia, foreign body sensation
• de-epithelialized area stains with fluorescein dye
• pain relieved with topical anesthetic

Complications
• infection, ulceration, recurrent erosion, secondary iritis

Treatment
• topical antibiotic (drops or ointment)
• consider topical NSAID (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch
• most abrasions clear spontaneously within 24-48 h
Recurrent Erosions

- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

Etiology

- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

Treatment

- as for corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 3 mo, topical lubrication
- bandage contact lens, anterior stromal puncture or phototherapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology

- local necrosis of corneal tissue due to infection
- infection is usually bacterial, rarely viral, fungal, or protozoan (Acanthamoeba)
- secondary to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features

- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications

- decreased vision, corneal perforation, iritis, endophthalmitis

Investigations

- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leaking will dilute the green stain at site of wound

Treatment

- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers)
- may be triggered by stress, fever, sun exposure, immunosuppression

Clinical Features

- pain, tearing, foreign body sensation, red eye, may have decreased vision, eyelid edema
- corneal hypoesthesia
- dendritic (thin and branching) lesion in epithelium that stains with fluorescein

Antiviral Treatment and Other Therapeutic Interventions for Herpes Simplex Virus Epithelial Keratitis

Cochrane DB Syst Rev 2010:12:CD002899

Rates of corneal re-epithelialization after acute HSV corneal epithelial keratitis are similar after treatment with trifluoridine or acyclovir, and significantly better than after treatment with idoxuridine or vidarabine. Brivudine and ganciclovir are not inferior to acyclovir. Combining an antiviral agent with Interferon or corneal epithelial debridement did not improve outcomes overall, but did hasten corneal healing. Debridement with concomitant antiviral treatment was more effective than debridement alone.

Antibiotic Treatment and Other Therapeutic Interventions for Herpes Simplex Virus Epithelial Keratitis

Cochrane DB Syst Rev 2010:12:CD002899

Rates of corneal re-epithelialization after acute HSV corneal epithelial keratitis are similar after treatment with trifluoridine or acyclovir, and significantly better than after treatment with idoxuridine or vidarabine. Brivudine and ganciclovir are not inferior to acyclovir. Combining an antiviral agent with Interferon or corneal epithelial debridement did not improve outcomes overall, but did hasten corneal healing. Debridement with concomitant antiviral treatment was more effective than debridement alone.
Complications
• corneal scarring (can lead to loss of vision)
• chronic interstitial keratitis due to penetration of virus into stroma
• secondary iritis, secondary glaucoma

Treatment
• topical antiviral such as trifluridine, consider systemic antiviral such as acyclovir
• dendritic debridement
• NO STEROIDS initially – may exacerbate condition
• ophthalmologist must exercise caution if adding topical steroids for chronic keratitis or iritis

Herpes Zoster
• dermatitis of the forehead (CN V1 territory) may involve globe
• Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then eye will be involved in ~75% of cases
• if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features
• pain, tearing, photophobia, red eye
• corneal edema, pseudodendrite, SPK
• corneal hypoesthesia

Complications
• corneal keratitis, ulceration, perforation and scarring
• secondary iritis, secondary glaucoma, cataract
• muscle palsies (rare) due to CNS involvement
• occasionally severe post-herpetic neuralgia

Treatment
• oral antiviral (acyclovir, valcyclovir, or famciclovir) immediately
• topical steroids, cycloplegia as indicated for keratitis, iritis
• erythromycin ointment if conjunctival involvement

Keratoconus
• bilateral paracentral thinning and bulging (ectasia) of the cornea to form a conical shape
• usually sporadic, but associated with Down's syndrome, atopy, contact lens use (theorized to be related to chronic vigorous eye rubbing)
• associated with breaks in Descemet's and Bowman's membrane
• results in irregular astigmatism, scarring, stromal edema

Treatment
• attempt correction with spectacles or contact lens
• cross-linking treatment may halt or slow disease progression
• intrastromal corneal ring segments can help flatten the corneal cone
• penetrating keratoplasty (corneal transplant) 90% successful
• post-transplant complications: endophthalmitis, graft rejection, graft failure, graft dehiscence

Arcus Senilis
• hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
• common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
• may be associated with hypercholesterolemia if age <40 yr, check lipid profile
• no associated visual symptoms, no complications, no treatment necessary

Kayser-Fleischer Ring
• brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
• due to deposition of copper pigment in Descemet's membrane
• associated with Wilson's disease
• no associated symptoms or complications of ring
• treat underlying disease
## The Uveal Tract

- Uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- Vascularized, pigmented middle layer of the eye, between the sclera and the retina

## Uveitis

- Uveal inflammation which may involve one, two, or all three parts of the tract
- Idiopathic or associated with autoimmune, infectious, granulomatous, malignant causes
- Should be managed by an optometrist or ophthalmologist
- Anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

### Table 6. Anatomic Classification of Uveitis

<table>
<thead>
<tr>
<th>Location</th>
<th>Etiology</th>
<th>Clinical Features</th>
<th>Complications</th>
<th>Treatment</th>
</tr>
</thead>
</table>
| Irritis  | Usually idiopathic  
|  | Connective tissue diseases  
|  | HLA-B27: reactive arthritis, ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease  
|  | Non-HLA-B27: juvenile idiopathic arthritis  
|  | Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster  
|  | Other: sarcoidosis, trauma, large abrasion, post ocular surgery  
|  | Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis  
|  | Usually unilateral  
|  | Usually idiopathic  
|  | Mostly idiopathic, secondary causes include sarcoidosis, Lyme disease, and multiple sclerosis  
|  | Bacterial: syphilis, tuberculosis  
|  | Viral: herpes simplex virus, CMV in AIDS  
|  | Fungal: histoplasmosis, candidiasis  
|  | Parasitic: toxoplasmosis (most common cause), toxocara  
|  | Immunosuppression may predispose to any of the above infections  
|  | Autoimmune: Behçet’s disease (triad of oral ulcers, genital ulcers, and posterior uveitis)  
|  | Malignancies (masquerade syndrome): metastatic lesions, malignant melanoma  
|  | Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA in severe cases with hypopyon), lacrimation  
|  | Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle)  
|  | Anterior chamber “cells” (WBC in anterior chamber due to anterior segment inflammation) and “flare” (protein precipitates in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic exudates inferiorly in the anterior chamber)  
|  | Occasionally keratic precipitates (clumps of cells on corneal endothelium)  
|  | Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis, or iritis from herpes simplex and zoster may cause an inflammatory glaucoma (trabeculitis)  
|  | Insidious onset of blurred vision, accompanied by vitreous floaters  
|  | Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric  
|  | Associated with anterior uveitis, most severe cases of secondary intermediate uveitis  
|  | Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells)  
|  | Posterior segment ‘snowbank’ = grey-white fibrovascular plaque at the pars plana  
|  | Painless as choroid has no sensory innervation  
|  | Often no conjunctival or scleral injection present  
|  | Decreased VA  
|  | Floaters (debris and inflammatory cells)  
|  | Vitreous cells and opacities  
|  | Hypopyon formation  
|  | Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents  
|  | Vitrectomy, cryotherapy, or laser photocoagulation to the “snowbank”  
|  | Systemic, topical, or sub-tenon  
|  | Systemic analgesia  
|  | If recurrent episodes, extensive medical workup may be indicated to rule out secondary causes  
|  | Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss)
**Lens**

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

**Cataracts**

- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, posterior subcapsular

**Etiology**
- acquired
  - age-related (over 90% of all cataracts)
  - cataract associated with systemic disease (may have juvenile onset)
    - DM
    - metabolic disorders (e.g. Wilson’s disease, galactosemia, homocystinuria)
    - hypocalcemia
  - traumatic (may be rosette shaped)
  - intraocular inflammation (e.g. uveitis)
  - toxic (steroids, phenothiazines)
  - radiation
- congenital
  - high myopia
  - present with altered red reflex or leukocoria
  - treat promptly to prevent amblyopia

**Clinical Features**
- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- “second sight” phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
  - patient may read without previously needed reading glasses
- diagnosis by slit-lamp exam, and by noting changes in red reflex using ophthalmoscope
- may impair view of retina during fundoscopy

**Treatment**
- medical: attempt correction of refractive error, no strong evidence suggesting benefit of vitamin supplementation
- surgical: definitive treatment
  - indications for surgery
    - to improve visual function in patients whose vision loss leads to functional impairment (no need to wait for “ripe” cataract, may postpone surgery as long as one eye has sufficient vision)
    - to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
    - congenital or traumatic cataracts
  - phacoemulsification (phaco = lens)
  - most commonly used surgical technique (see Surgical Ophthalmology, OP44)
  - femtosecond laser for the anterior capsulotomy and fragmentation of the lens
- post-operative complications
  - RD, endophthalmitis, dislocated IOL, macular edema, glaucoma
  - with new foldable IOLs that have truncated edges, <10% of patients get posterior capsular opacification, which should be treated with YAG laser

**Prognosis**
- excellent if not complicated by other ocular disease
**Dislocated Lens (Ectopia Lentis)**

**Etiology**
- associated with Marfan’s Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic

**Clinical Features**
- decreased VA
- may get monocular diplopia
- iridodensis (quivering of iris with movement)
- direct ophthalmoscopy may elicit abnormal red reflex

**Complications**
- cataract, glaucoma, uveitis

**Treatment**
- surgical correction ± lens replacement

---

**Vitreous**

- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

---

**Posterior Vitreous Detachment**

**Etiology**
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

**Clinical Features**
- floaters, flashes of light

**Complications**
- traction at areas of abnormal vitreoretinal adhesions may cause retinal tears/detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

**Treatment**
- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

---

**Vitreous Hemorrhage**

- bleeding into the vitreous cavity

**Etiology**
- PDR
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

**Clinical Features**
- sudden loss of VA
- may be preceded by "shower" of many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

**Treatment**
- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no RD), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser to possible bleeding sites/vessels

---

**Floaters:** "bugs", "cobwebs", or "spots" of vitreous condensation that change with eye position

**Weiss Ring:** formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

**Weiss Ring:** formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

**Vitreous Hemorrhage in a Child:** Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse

Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment

---

**Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse**
**Endophthalmitis and Vitritis**

- intraocular infection: acute, subacute, or chronic

**Etiology**
- most commonly a post-operative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

**Clinical Features**
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

**Treatment** (see *Ocular Trauma, OP42*)
- OCULAR EMERGENCY: presenting vision best indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

**Retina**
- composed of two parts (Figure 2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
  - retinal pigmented epithelium (RPE) layer: external to neurosensory retina
  - macula: rich in cones (for colour vision); most sensitive area of retina; looks darker due to increased luteal pigment, lack of retinal vessels, and thinning of retina in this region; 15° temporal and slightly below the optic disc
  - fovea: centre of macula; responsible for detail, fine vision
  - optic disc: slightly oval vertically, pinkish colour with centrally depressed yellow cup (normal C:D ratio is ≤0.4), retinal artery and vein pass through cup
  - ora serrata: irregularly-shaped, anterior margin of the retina (can only be visualized with indirect ophthalmoscopy of the far peripheral retina, or through a Goldmann 3 mirror lens)

**Central Retinal Artery Occlusion**

**Etiology**
- emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
- thrombus
- temporal arteritis

**Clinical Features**
- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)
- fundoscopy
  - "cherry-red spot"
  - retinal pallor
  - narrowed arterioles, boxcarring (segmentation of blood in arteries)
  - cotton wool spots (retinal infarcts)
  - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations
  - after ~6 wk cherry-red spot recedes and optic disc pallor becomes evident

**Treatment**
- OCULAR EMERGENCY: attempt to restore blood flow within 2 h
  - the sooner the treatment = better prognosis (irreversible retinal damage if >90 min of complete CRAO)
  - massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
  - decrease IOP
    - topical β-blockers
    - inhaled oxygen-carbon dioxide mixture
    - IV acetazolamide
    - IV mannitol (draws fluid from eye)
    - drain aqueous fluid – anterior chamber paracentesis (carries risk of infection, lens puncture)
    - Nd:YAG laser embolectomy
    - intra-arterial or intra-venous thrombolysis
Branch Retinal Artery Occlusion

- only part of the retina becomes ischemic resulting in a visual field loss
- more likely to be of embolic etiology than CRAO; need to search for source
- management: ocular massage to dislodge embolus if VA is affected

Central/Branch Retinal Vein Occlusion

- second most frequent “vascular” retinal disorder after DR
- usually a manifestation of a systemic disease (e.g. HTN, DM)
- thrombus occurs within the lumen of the blood vessel

Predisposing Factors

- arteriosclerotic vascular disease
- HTN
- DM
- glaucoma
- hyperviscosity (e.g. polycythemia rubra vera, sickle-cell disease, lymphoma, leukemia)
- drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features

- painless, monocular, gradual or sudden vision loss
- ± RAPD
- fundoscopy
  - “blood and thunder” appearance
  - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA ~20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula intact
  - hemorrhagic/ischemic retinopathy
    - usually older patient with deficient arterial supply
    - RAPD, VA ~20/200, reduced peripheral vision
    - more hemorrhages, cotton wool spots, congestion
    - poor visual prognosis

Complications

- degeneration of RPE
- neovascularization of retina and iris (secondary rubeosis), leading to secondary glaucoma
- vitreous hemorrhage
- macular edema

Treatment

- no treatment available to restore vision in CRVO/BRVO
- treat underlying cause/contributing factor
- fluorescein angiography to determine extent of retinal non-perfusion (risk of neovascularization)
- retinal laser photocoagulation, or intravitreal anti-VEGF injection to reduce retinal or iris neovascularization and prevent neovascular glaucoma
- macular grid laser photocoagulation for the treatment of macular edema in BRVO, not CRVO, intravitreal or slow-release biodegradable corticosteroid, or anti-VEGF injection is effective in the treatment of macular edema in both CRVO and BRVO

Retinal Detachment

- cleavage in the plane between the neurosensory retina and the RPE
- three types
  - rheumatogenous (most common)
    - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tears may be caused by PVD, degenerative retinal changes, trauma, or iatrogenically
    - incidence increases with advancing age, in high myopes, and after ocular surgery/truma
  - tractional
    - caused by traction (due to vitreal, epiretinal, or subretinal membrane) pulling the neurosensory retina away from the underlying RPE
    - found in conditions such as DR, CRVO, sickle cell disease, ROP, and ocular trauma
  - exudative
    - caused by damage to the RPE resulting in fluid accumulation in the subretinal space
    - main causes are intraocular tumours, posterior uveitis, central serous retinopathy

Efficacy and Safety of Widely Used Treatments for Macular Oedema Secondary to Retinal Vein Occlusion: A Systematic Review

Purpose: To assess the efficacy of widely used treatments for macular oedema (MO) secondary to retinal vein occlusion (RVO). MO secondary to RVO can cause vision loss due to blockage of the central retinal vein (CRVO) or a branch retinal vein (BRVO).

Outcomes: Mean change in best corrected visual acuity (BCVA) from baseline and/or number of patients gaining at least 10 letters from baseline to 6 mo or equivalent time point.

Results: 14 unique RCTs identified. Ranibizumab 0.5 mg produced greater improvements in BCVA at 6 mo compared to sham in BRVO (mean difference 11 letters; 95% CI 7.83-14.17) and CRVO (mean difference 14 letters; 95% CI 10.51-17.98). Improvements in BCVA were also observed with dexamethasone intravitreal implant (IVT) 0.7 mg compared with sham in patients with BRVO or CRVO (mean difference 2.5 letters; 95% CI 0.7-4.3). The difference was significant with BRVO alone, but not CRVO alone. At 36 mo in a large prospective RCT, a greater proportion of patients with BRVO gained >15 letters with laser therapy versus no treatment (OR 3.16; 95% CI 1.25-8.00), whereas no difference was observed in a 9 mo end point smaller study. Three studies showed no benefit for laser therapy in CRVO.

Conclusions: Both ranibizumab and dexamethasone IVT show significant improvements over previously accepted standard of care (laser therapy) for the treatment of BRVO and CRVO.

The “blood and thunder” appearance on fundoscopy is very characteristic of a CRVO

There is an 8-10% risk of developing CRVO or BRVO in other eye

GENEVA Phase 3 Trials in BRVO and CRVO

Optimally to 117:1134-146
Randomized sham-controlled trial of dexamethasone intravitreal implant in patients with macular edema due to retinal vein occlusion.
Dexamethasone intravitreal implant reduces the risk of vision loss and improves the speed and incidence of visual improvement in eyes with macular edema 2° to BRVO and CRVO.

Superotemporal retina is the most common site for horseshoe tears
Clinical Features
• sudden onset
• flashes of light
  - due to mechanical stimulation of the retinal photoreceptors
• floaters
  - hazy spots in the line of vision which move with eye position, due to drops of blood from torn vessels bleeding into the vitreous
• curtain of blackness/ peripheral field loss
  - darkness in one field of vision when the retina detaches in that area
• loss of central vision (if macula “off”)
• decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
• ophthalmoscopy: detached retina is grey-white with surface blood vessels, loss of red reflex
• ± RAPD

Treatment
• prophylactic: symptomatic tear (floaters or floaters) can be sealed off with laser/cryotherapy, with the goal of preventing progression to detachment
• therapeutic
  - rhegmatogenous
    - scleral buckle procedure (see Surgical Ophthalmology, OP44)
    - pneumatic retinopexy (see Surgical Ophthalmology, OP44)
    - both treatments above are used in combination with localization of retinal tears/holes and subsequent treatment with cryotherapy or laser to create adhesions between the RPE and the neurosensory retina
  - vitrectomy plus injection of gas or silicone oil in cases of recurrent detachment
  - tractional
    - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
  - exudative
  - treat underlying cause

Complications
• loss of vision, vitreous hemorrhage, recurrent RD
• a RD is an emergency, especially if the macula is still attached (macula “on”)
• prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Retinitis Pigmentosa
• worldwide incidence between 1/3,500 and 1/7,000 people
• many forms of inheritance, most commonly autosomal recessive (60%)
• hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy

Clinical Features
• night blindness, decreased peripheral vision (“tunnel vision”), decreased central vision (macular changes), glare (from posterior subcapsular cataracts, common)

Investigations
• fundoscopy: areas of “bone-spicule” pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
• electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

Treatment
• no treatments available to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients

Leber’s Congenital Amaurosis
• worldwide incidence 1/80,000
• inherited degeneration, autosomal recessive

Clinical Features
• symptoms: resting nystagmus, sluggish or no pupillary response, severe vision loss/blindness

Investigations
• diagnosis: 11 types, confirmed by genetic testing

Treatment
• no treatments available to reverse the conditions for most forms; one form (LCA2) shown to be successfully treatable by gene replacement using adeno-associated virus
Age-Related Macular Degeneration

- leading cause of irreversible blindness in the western world, associated with increasing age, usually bilateral
- 10% of people >65 yr old have some degree of AMD
- F>M
- degenerative changes are concentrated at the macula, thus only central vision is lost; peripheral vision (important for navigation) is maintained so patients can usually maintain an independent lifestyle

Classification

- Non-Exudative/“Dry” (Non-Neovascular) AMD
  - most common type of AMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow-white deposits between the RPE and Bruch’s membrane (area separating inner choroidal vessels from RPE)
  - RPE atrophy: coalescence of depigmented RPE, clumps of focal hyperpigmentation, or hypopigmentation
  - may progress to neovascular AMD

- Exudative/“Wet” (Neovascular) AMD
  - 10% of AMD, but 80% of AMD that results in severe vision loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch’s membrane causing subsequent growth and proliferation of choroidal capillaries
  - may lead to serous detachment of overlying RPE and retina, hemorrhage and lipid precipitates into subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of hemorrhagic RD
  - leads to disciform scarring and severe central vision loss

Risk Factors

- female
- increasing age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features

- variable degree of progressive central vision loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations

- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess type and location of choroidal neovascularization – pathologic new vessels leak dye
- OCT retinal imaging

Treatment

- non-neovascular “dry” AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study (AREDS) and Age-related Eye Disease Study 2 (AREDS2) in sidebar
- neovascular “wet” AMD
  - see Common Medications, OP44
    - intravitreal injection of anti-VEGF
      - pegaptanib (Macugen*), ranibizumab (Lucentis*), bevacizumab (Avastin*), afibercept (Eylea*) (see VEGF Inhibitors, OP45)
    - laser photocoagulation for neovascularization
    - no definitive treatment for disciform scarring
    - PDT with verteporfin (Visudyne*)
      - IV injection of verteporfin followed by low intensity laser to area of choroidal neovascularization
  - see Age-Related Eye Disease Study (AREDS)
  - AREDS studied the effect of high-dose combination of vitamin C, vitamin E, β-carotene, and zinc in patients with and without AMD. Those who are already affected by AMD showed 19% decrease in risk of further visual loss, whereas high dose supplementation showed no benefit in patients with early or no AMD.

Wet AMD Lesions on Fluorescein Angiography

- Classic: well-defined leakage
- Occult: mottled or ill-defined leakage

Drusen vs. Exudate

- Drusen: hyaline material secreted by RPE seen frequently in AMD specifically in perimacular region
- Hard/Soft Exudates: lipid deposits in the retina associated with DR and HTN

Age-Related Eye Disease Study 2 (AREDS2)

  - Addition of lutein + zeaxanthin, DHA + EPA, or both to the AREDS formulation in primary analyses didn’t reduce risk of progression to advanced AMD. However, because of the potential increased incidence of lung cancer in former smokers, lutein + zeaxanthin could be an appropriate carotenoid substitute in the AREDS formulation.

Age-Related Macular Degeneration

- CATT Research Group. NEJM 2011;364:1897-1908
  - Study: A multicentre, single-blind, randomized control trial comparing the effects of ranibizumab and bevacizumab on visual acuity in patients with age-related macular degeneration (AMD).
  - Patients: 1,208 patients aged 50 or more with previously untreated AMD and visual acuity between 20/25 and 20/300.
  - Intervention: Intravitreal injections of ranibizumab vs. intravitreal injections of bevacizumab.
  - Results: The monthly use of either bevacizumab or ranibizumab results in the same visual acuity outcome. This finding holds true for the mean visual acuity and the proportion of patients who gain 15 letters, lose 15 letters, or remain stable.
  - Equivalent visual acuity outcomes were observed with both the monthly and the as-needed regimens of ranibizumab.
  - Conclusion: This study supports the use of either bevacizumab or ranibizumab for the treatment of neovascular AMD. The continued global use of intravitreal bevacizumab is an equally effective, low-cost alternative to ranibizumab.

- Intravitreal bevacizumab and ranibizumab for Neovascular Age-Related Macular Degeneration
  - CATT Research Group. NEJM 2011;364:1897-1908

  - Equivalent visual acuity outcomes were observed with both the monthly and the as-needed regimens of ranibizumab.
  - Conclusion: This study supports the use of either bevacizumab or ranibizumab for the treatment of neovascular AMD. The continued global use of intravitreal bevacizumab is an equally effective, low-cost alternative to ranibizumab.
Glaucoma

Definition
- progressive optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

Background
- aqueous is produced by the ciliary body and flows from the posterior chamber to the anterior chamber through the pupil, and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm
- an isolated increase in IOP is termed OHT (or glaucoma suspect) and these patients should be followed for increased risk of developing glaucoma (10% if IOP 20-30 mmHg; 40% if IOP 30-40 mmHg; and most if IOP >40 mmHg)
- pressures >21 mmHg are more likely to be associated with glaucoma; however, up to 50% of patients with glaucoma do not have IOP >21 mmHg
- loss of peripheral vision most commonly precedes central loss
- sequence of events: gradual pressure rise → increased C:D ratio → visual field loss

Investigations
- medical and family history
- VA testing
- slit-lamp exam to assess anterior chamber depth with gonioscopic lens to assess angle patency
- ophthalmoscopy to assess the disc features
- tonometry by applanation or indentation to measure IOP
- visual field testing
- pachymetry to measure corneal thickness
- future follow-up includes optic disc examination, IOP measurement, and visual field testing to monitor course of disease

Ten Year Follow-Up of Age-Related Macular Degeneration in the Age-Related Eye Disease Study: AREDS Report No. 36

Study: Randomized clinical trial.
Objective: To describe 10 yr progression rates to intermediate or advanced AMD.
Patients: Age-related eye disease study (AREDS) participants were observed for an additional 5 yr after RCT completion. Participants aged 55-80 yr with no AMD or AMD of varying severity (n = 4,757) were followed up in the AREDS trial for a median duration of 6.5 yr. When the trial ended, 3,549 of the 4,203 surviving participants were followed for 5 additional yr.
Intervention: Treatment with antioxidant vitamins and minerals.
Main Outcome: Development of varying stages of AMD and changes in visual acuity.
Results: The risk of progression to advanced AMD increased with increasing age (p<0.01) and severity of drusen. Women (p=0.005) and current smokers (p<0.001) were at increased risk of neovascular AMD. In the oldest participants with the most severe AMD status at baseline, the risks of developing neovascular AMD and central geographic atrophy by 10 yr were 46.1% and 26.0%, respectively. Similarly, rates of progression to large drusen increased with increasing severity of drusen at baseline, with 70.9% of participants with bilateral medium drusen progressing to large drusen and 13.8% to advanced AMD in 10 yr. Median visual acuity at 10 yr in eyes that had large drusen at baseline but never developed advanced AMD was 20/25; eyes that developed advanced AMD had a median visual acuity of 20/200.
Conclusion: The natural history of AMD demonstrates relentless loss of vision in persons who developed advanced AMD.

Average IOP = 15 ± 3 mmHg
Normal C:D ≤0.4
Suspect glaucoma if C:D ratio >0.6, C:D ratio differs between eyes by >0.2, or cup approaches disc margin

© Diana Dai 2005
Primary Open-Angle Glaucoma

- most common form, >95% of all glaucoma cases
- due to obstruction of aqueous drainage within the trabecular meshwork and its drainage into the Canal of Schlemm
- insidious and asymptomatic, screening is critical for early detection

Major Risk Factors
- elevated IOP (>21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic
- thin central cornea (OHTS trial)

Minor Risk Factors
- myopia
- HTN
- DM
- hyperthyroidism (Graves’ disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

Clinical Features
- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased C:D ratio (vertical C:D >0.6)
  - significant C:D asymmetry between eyes (>0.2 difference)
  - thinning, notching of the neuroretinal rim
  - flame shaped disc hemorrhage
  - 360° of peripapillary atrophy
  - nerve fibre layer defect
  - large vessels become nasally displaced
- visual field loss
  - slow, progressive, irreversible loss of peripheral vision
  - paracentral defects, arcuate scotoma, and nasal step are characteristics (Figure 19)
  - late loss of central vision if untreated

Treatment
- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see Glaucoma Medications, Table 12, OP45)
  - increase aqueous outflow
    - topical cholinergics
    - topical prostaglandin analogues
    - topical α-adrenergics
  - decrease aqueous production
    - topical β-blockers
    - topical and oral carbonic anhydrase inhibitor
    - topical α-adrenergics
  - laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
  - trabeculectomy or minimally invasive glaucoma surgery (MIGS) (see Surgical Ophthalmology, OP44)
  - serial optic nerve head examinations, IOP measurements, and visual field testing to monitor disease course

Normal Tension Glaucoma

- POAG with IOP in normal range
- often found in women >60 but may occur earlier
- associated with migraines, peripheral vasospasm, systemic nocturnal hypotension, sleep apnea
- damage to optic nerve may be due to vascular insufficiency

Treatment
- treat reversible causes
**Secondary Open Angle Glaucoma**

- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork
  - steroid-induced glaucoma
  - traumatic glaucoma
  - pigmentary dispersion syndrome
  - pseudoexfoliation syndrome

**Primary Angle-Closure Glaucoma**

- 5% of all glaucoma cases
- peripheral iris bows forward in an already susceptible eye with a shallow anterior chamber obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block, and results in inability of the aqueous to flow from the posterior chamber to the anterior chamber resulting in a sudden rise in IOP

**Risk Factors**

- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

**Clinical Features**

- red, painful eye = RED FLAG
- unilateral, but other eye increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- corneal edema with conjunctival injection
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

**Complications**

- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synechiae, resulting in permanent angle closure

**Treatment**

- **OCULAR EMERGENCY:** refer to ophthalmologist for acute angle closure glaucoma
  - aqueous suppressants and hyperosmotic agents
  - medical treatment (see Glaucoma Medications, Table 12, OP45)
    - miotic drops (pilocarpine) to reverse pupillary block
    - decrease IOP
      - topical β-blockers
      - topical adrenergics
      - topical cholinergics
        - pilocarpine 1-4% q15min, up to q5min
      - systemic carbonic anhydrase inhibitors
        - IV acetazolamide 250-500 mg
      - systemic hyperosmotic agents
        - oral glycerine 1 g/kg
        - IV mannitol 1 g/kg
      - laser iridotomy

**Secondary Angle-Closure Glaucoma**

**Uveitis**

- inflamed iris adheres to lens (posterior synechiae)

**Neovascular Glaucoma**

- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris vessels

---

**Rule of Fours**

1/4 of general population using topical steroid for 4 wk, 4 x/d will develop an increase in IOP

**Collaborative Normal Tension Glaucoma Study**

**Cochrane systematic review of 26 trials and meta-analysis of 10 trials investigating the effectiveness of topical pharmacological therapies for POAG or OHT.**

- Patients: 4,979 participants randomized in 26 trials. Patients had OHT with IOP >21 mmHg or open angle glaucoma.
- Intervention: Topical eye medications, including β-blockers, dorzolamide, brimonidine, pilocarpine, and epinephrine vs. each other and placebo.
- Main Outcome: Reduction of progression or prevention of onset of visual field defects.
- Results: Meta-analysis on all trials that tested drops against placebo or untreated controls demonstrated that lowering IOP reduces incidence of glaucomatous visual field defects, with an odds ratio of 0.62 (95% CI 0.47-0.81). However, this result is of limited practical use since different therapies were pooled. No single drug demonstrated significant visual field protection.
- Conclusion: Lowering IOP cannot prevent progression of visual field defects in patients with OHT.
Pupils

• pupil size is determined by the balance between the sphincter muscle and the dilator muscle
  • sphincter muscle is innervated by the parasympathetic nervous system
    ▪ carried by CN III: pre- and post-ganglionic fibres synapse in ciliary ganglion, and use acetylcholine as the neurotransmitter
  • dilator muscle is innervated by the sympathetic nervous system (SNS)
    ▪ first order neuron = hypothalamus → brainstem → spinal cord
    ▪ second order/preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
    ▪ third order/postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is norepinephrine
      • as a diagnostic test, 4-10% cocaine prevents the re-uptake of norepinephrine, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner's Syndrome)
      • see Neurology, Figure 8, N8

Pupillary Light Reflex

• light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
• impulses enter bilaterally in midbrain via pretectal area and Edinger-Westphal nuclei
• nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes
  α1 – Pupillary dilator muscle contraction (Mydriasis)
  β2 – Ciliary muscle relaxation (Non-accommodation); increased aqueous humor production
  M3 – Pupillary sphincter contraction (Miosis); increased ciliary muscle contraction (Accommodation)

Pupil Abnormalities

Denervation Hypersensitivity
• when post-ganglionic fibers are damaged, the understimulated end-organ attempts to compensate by developing an excess of neuroreceptors and becomes hypersensitive
• postganglionic parasympathetic lesions (i.e. Adie's pupil)
  ▪ pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
• postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner's syndrome)
  ▪ pupil will dilate with 0.125% epinephrine, normal pupil will not

Local Disorders of Iris
• posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
• ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
• trauma (e.g. post-intraocular surgery)

Anisocoria
• unequal pupil size
• idiopathic/physiologic anisocoria
  ▪ 20% of population
  ▪ round, regular, <1 mm difference
  ▪ pupils reactive to light and accommodation
  ▪ responds normally to mydriatics/miotics
• post eye surgery
• see Table 7 for other causes of anisocoria

5 Targets of Retinal Signals
• Pre-tectal nucleus (pupillary reflex/eye movements)
• Lateral geniculate body of thalamus
• Superior colliculus (eye movements)
• Suprachiasmatic nucleus (optokinetic)
• Accessory optic system (circadian rhythm)
**Table 7. Summary of Conditions Causing Anisocoria**

**Figure 22. Approach to anisocoria**
Dilated Pupil (Mydriasis)

**Sympathetic Stimulation**
- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

**Parasympathetic Understimulation**
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, DM (may spare pupil), trauma
  - CN III palsy will respond to drugs (e.g. pilocarpine), unlike a pupil dilated from medication (mydriatics)

**Acute Angle-Closure Glaucoma**
- fixed, mid-dilated pupil

**Adie's Tonic Pupil**
- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- if decreased deep tendon reflexes may be Adie's syndrome
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
  - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie's pupils are smaller than unaffected eye

**Trauma**
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

Constricted Pupil (Miosis)

**Senile Miosis**
- decreased sympathetic stimulation with age

**Parasympathetic Stimulation**
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

**Horner's Syndrome**
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis, anhydrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of norepinephrine) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates norepinephrine release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- postganglionic lesions result in denervation hypersensitivity, which will cause pupil to dilate with 0.125% epinephrine, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumour, Pancoast tumour, goitre, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabes dorsalis, cervical vertebral fractures

**Iritis**
- miotic pupil initially
- later, may be irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light
Argyll-Robertson Pupil
• both pupils irregular and <3 mm in diameter, ± ptosis
• does not respond to light stimulation
• responds to accommodation (light-near dissociation)
• suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

Other Causes
• optic neuritis, retinal lesions

Relative Afferent Pupillary Defect

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light, caused by a lesion in visual afferent (sensory) pathway anterior to optic chiasm
- differential diagnosis: large RD, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, optic neuritis (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
  - if the light is moved quickly from the unaffacted eye to the affected eye, “paradoxical” dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye
Malignancies

- uncommon site for 1° malignancies
- eye usually affected secondarily by cancer or cancer treatments
- see Retinoblastoma, OP41

Lid Carcinoma

Etiology
- basal cell carcinoma (rodent ulcer) (90%)
  - spread via local invasion, rarely metastasizes
  - ulcerated centre, indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
  - spread via local invasion, may also spread to nodes and metastasize
  - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
  - often masquerades as chronic blepharitis or recurrent chalazion
  - highly invasive, metastasize
  - Kaposi's sarcoma, malignant melanoma, Merkel cell tumour, metastatic tumour

Treatment
- incisional or excisional biopsies
- may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
- surgical reconstruction

Malignant Melanoma

- most common 1° intraocular malignancy in adults
- more prevalent in Caucasians
- arise from uveal tract, 90% choroidal melanoma
- hepatic metastases predominate

Treatment
- imaging to investigate spread
- depending on the size of the tumour, either radiotherapy, enucleation, limited surgery

Metastases

- most common intraocular malignancy in adults
- most commonly from breast and lung in adults, neuroblastoma in children
- usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
- may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

Treatment
- local radiation, chemotherapy
- enucleation if blind, painful eye

Ocular Manifestations of Systemic Disease

HIV/AIDS

- up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs
- Kaposi's sarcoma
  - secondary to human herpes virus 8 (HHV-8), affects conjunctiva of lid or globe
  - numerous vascular skin malignancies
  - differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma
- multiple molluscum contagiosum
- herpes simplex keratitis
- herpes zoster keratitis
Retina
- HIV retinopathy (most common)
  - cotton wool spots in >50% of HIV patients
  - intraretinal hemorrhage
- CMV retinitis
  - ocular opportunistic infection that develops in late stages of HIV when severely immunocompromised (CD4 count ≤50)
  - a necrotizing retinitis, with retinal hemorrhage and vasculitis, “brushfire” or “pizza pie” appearance
  - presents with scotomas (macular involvement and RD), blurred vision, and floaters
  - untreated infection will progress to other eye in 4-6 wk
  - treatment: virostatic agents (e.g. gancyclovir or foscarnet) via IV or intravitreal injection
- necrotizing retinitis
  - from herpes simplex virus, herpes zoster, toxoplasmosis
- disseminated choroiditis
  - *Pneumocystis carinii, Mycobacterium avium intracellulare, Candida*

Other Systemic Infections
- herpes zoster
  - see *Herpes Zoster, OP19*
- candidal endophthalmitis
  - fluffy, white-yellow, superficial retinal infiltrate that may eventually result in vitritis
  - may present with inflammation of the anterior chamber
  - treatment: systemic amphotericin B, oral fluconazole
- toxoplasmosis
  - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous infiltration (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by *Toxoplasma gondii* protozoa transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folic acid, or clindamycin. Consider adding steroids if severe inflammation (vitritis, macular or optic nerve involvement)

Diabetes Mellitus
- see *Endocrinology, E7*
- most common cause of blindness in young people in North America
- consider DM if unexplained retinopathy, cataract, extraocular muscle palsy, optic neuropathy, sudden change in refractive error
- loss of vision due to
  - progressive microangiopathy leading to macular edema
  - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
  - rubecosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

DIABETIC RETINOPATHY

Background
- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - microaneurysms
  - dot and blot hemorrhages
  - hard exudates (lipid deposits), non-specific for DR
  - macular edema
- advanced non-proliferative (or pre-proliferative)
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, leaky vessels within the retina
    - cotton wool spots (nerve fibre layer infarcts)
- proliferative
  - 5% of patients with DM will reach this stage
- neovascularization of iris, disc, retina to vitreous
- neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
- vitreous hemorrhage from bleeding, fragile new vessels, fibrous tissue can contract causating tractional RD
- high risk of severe vision loss secondary to vitreous hemorrhage, RD

Screening Guidelines for Diabetic Retinopathy
- type 1 DM
  - screen for retinopathy beginning annually 5 yr after disease onset
  - annual screening indicated for all patients over 12 yr and/or entering puberty
- type 2 DM
  - initial examination at time of diagnosis, then annually
- pregnancy
  - ocular exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
- gestational diabetics are not at risk for DR

Treatment
- Diabetic Control and Complications Trial (DCCT)
- tight control of blood sugar decreases frequency and severity of microvascular complications
- blood pressure control
- focal laser for clinically significant macular edema
- intravitreal injection of corticosteroid or anti-VEGF for foveal involved diabetic macular edema
- panretinal laser photocoagulation for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
- vitrectomy for non-clearing vitreous hemorrhage and tractional RD in PDR

Lens Changes
- earlier onset of senile nuclear sclerotic and cortical cataracts
- may get hyperglycemic cataract, due to sorbitol accumulation (rare)
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters

Extraocular Muscle Palsy
- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

Optic Neuropathy
- visual acuity loss due to infarction of optic disc/nerve

![Figure 25. DM vs. HTN retinopathy](image-url)
Hypertension

- retinopathy is the most common ocular manifestation
- chronic HTN retinopathy: arteriovenous (AV) nicking, blot retinal hemorrhages, microaneurysms, cotton wool spots
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema

Multiple Sclerosis

- see Neurology, N54

Clinical Features

- blurred vision and decreased colour vision: secondary to optic neuritis
- central scotoma: due to damage to papillomacular bundle of retinal nerve fibres
- diplopia: secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment

- IV steroids with taper to oral form for optic neuritis
  - DO NOT treat with oral steroids in isolation as this increases likelihood of eventual development of MS

TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

Graves’ Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur secondary to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, ptosis and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)
**Giant Cell Arteritis/Temporal Arteritis**

- see Rheumatology, RH20

**Clinical Features**
- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and past medical history of polymyalgia rheumatica
- ischemic optic atrophy
  - 50% lose vision in other eye if untreated

**Diagnosis**
- temporal artery biopsy + increased ESR (ESR can be normal, but likely 80-100 in first hour), increased CRP
- if biopsy of one side is negative, biopsy the other side

**Treatment**
- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation (DO NOT WAIT TO TREAT)

**Sarcoidosis**

- granulomatous uveitis with large "mutton fat" keratitic precipitates and posterior synechiae
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

**Treatment**
- steroids and mydriatics

**Pediatric Ophthalmology**

**Strabismus**

- ocular misalignment in one or both eyes, found in 3% of children
- object not visualized simultaneously by fovea of each eye
- terms used to describe strabismus depend upon
  - direction of deviation relative to the correctly fixing eye
  - conditions under which it presents: 'latent', 'manifest' misalignment
  - change with the position of gaze: 'comitant' (usually nonparalytic), 'incomitant' (usually occurs with paralytic or restrictive strabismus)
- often presents with parental concern about a wandering eye, crossing eye, or poor vision
- elicit a detailed family history of strabismus, amblyopia, type of eyeglasses and history of wear, extraocular muscle surgery or other eye surgery, and genetic diseases to identify children at higher risk
- distinguish from pseudostrabismus (prominent epicantial folds, hypertelorism, markedly positive or negative angle κ)
- complications: amblyopia, cosmesis

**HETEROTROPIA**

- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

**Types**

- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = "crossed-eyes"; exotropia = "wall-eyed"

**Differentiate from Pseudostrabismus**

- prominent epicantial folds: give appearance of esotropia but Hirschberg test is normal, more common in Asians
- markedly elevated angle κ (the angle formed by the pupillary axis and the visual axis at the centre of the pupil)
  - caused by the failure of optical axis of the eye and the visual axis to coincide
  - a small positive (up to 5°) angle κ is physiologic
  - a large positive angle κ (nasally deviated fovea) simulates eso-appearance
  - a large negative angle κ (temporally deviated fovea) gives an exo-appearance
Tests
- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - light reflex lateral to central cornea indicates esodeviation; light reflex medial to central cornea indicates exodeviation
  - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle $\kappa$)
- cover test
- the deviation can be quantified using prisms

HETEROPHORIA
- latent deviation
- deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- Hirschberg test will be normal (light reflex symmetrical)
- very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Tests
- cover-uncover test
- alternate cover test
  - alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - maintain cover over one eye for 2-3 s before rapidly shifting to other eye

Table 9. Paralytic vs. Non-Paralytic Strabismus

<table>
<thead>
<tr>
<th>Clinical Characteristics</th>

</tbody>
</table>
Accommodative Esotropia
- normal response to approaching object is the triad of the near reflex: convergence, accommodation and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

Non-accommodative Esotropia
- accounts for 50% of childhood strabismus
- most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

Amblyopia

Definition
- a neurodevelopmental visual disorder with unilateral (or less commonly, bilateral) reduction of best corrected visual acuity that cannot be attributed only and directly to the effect of a structural abnormality of the eye. It is caused by abnormal visual experience early in life and cannot be remedied immediately by spectacle glasses alone
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia). Other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors), and concomitant structural ocular problems

Detection
- “Holler Test”: young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
- prognosis: 90% will have good vision restored and maintained if treated <4 yr old

Etiology and Management
- strabismus
  - correct with glasses for accommodative esotropia (50% of children experience relief of their esotropia with glasses and will not require surgery)
  - occlusion of unaffected eye forces brain to use previously strabismic eye; aims to bring vision in previously suppressed eye to normal before surgery
  - surgery: recession (weakening) – moving muscle insertion further back on the globe; or resection (strengthening) – shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until ~8 yr of age
- anisometropia
  - amblyopia usually in the more hyperopic eye
  - the more emmetropic (normal refraction) eye receives a clear image while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if visual acuity difference persists after 4-8 wk of using glasses
- deprivation amblyopia
  - occlusion due to ptosis, cataract, retinoblastoma, corneal opacity
  - occlusion amblyopia: prolonged patching of good eye may cause it to become amblyopic

Occlusion Therapy
- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision
- atropine cycloplegic drops to impair accommodation and blur vision of the better seeing eye

Risks
- permanent loss of vision in the affected eye
- possibility of injury to ‘remaining’ good eye
  - safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is <20/50
- loss of stereopsis
Leukocoria

- white reflex (red reflex is absent)

Differential Diagnosis
- cataract
- retinoblastoma
- retinal coloboma
- ROP
- persistent hyperplastic primary vitreous
- Coats' disease (exudative retinal telangiectasis)
- toxocariasis
- RD

Retinoblastoma

- most common primary intraocular malignancy in children
- incidence: 1/15,000; sporadic or genetic transmission; screening of siblings/offspring essential
- unilateral (2/3) or bilateral (1/3)
- malignant – direct or hematogenous spread
- diagnosis
  - often presents with leukocoria or strabismus
  - U/S or CT scan may demonstrate calcified mass (present in most cases)

Treatment
- radiotherapy, chemotherapy combined with laser, cryopexy, and/or enucleation

Retinopathy of Prematurity

- vasoproliferative retinopathy that is a major cause of blindness in the developed world

Risk Factors
- non-black race (black infants have lower risk of developing ROP)
- low gestational age, birth weight <1500 g
- high oxygen exposure after birth (iatrogenic)

Classification (ROP Staging)
- stage 1: faint demarcation line at the junction between the vascularized and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula "on", 4B: macula "off")
- stage 5: total RD
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with 5 continuous or 8 cumulative clock hours of ROP involvement

Treatment
- threshold disease is treated with cryotherapy or laser (laser is now the standard treatment, with better refractive outcome), off label anti-VEGF intravitreal injections
- ROP beyond threshold level is either watched carefully (usually stage 4A) or treated with vitrectomy/scleral buckle

Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

Nasolacrimal System Defects

- congenital obstruction of the nasolacrimal duct (failure of canalization), usually occurs at 1-2 mo of age
- epiphora, crusting, discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac

Treatment
- massage over lacrimal sac at medial corner of eyelid
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing
**Ophthalmia Neonatorum**

- newborn conjunctivitis in first mo of life
- causes
  - toxic: silver nitrate, erythromycin
  - infectious: bacterial (e.g. *N. gonorrhoeae* – most common, *C. trachomatis*), herpes simplex virus
- diagnose using stains and cultures

**Treatment**

- systemic antibiotics with possible hospitalization if infectious etiology
- topical prophylaxis, most commonly with erythromycin (or silver nitrate), is required by law at birth

**Congenital Glaucoma**

- due to inadequate development of the filtering mechanism of the anterior chamber angle

**Clinical Features**

- cloudy cornea, increased IOP
- photophobia, epiphora
- buphthalmos (large cornea, “ox eye”, secondary to increased IOP), blepharospasm

**Treatment**

- filtration surgery is required soon after birth to prevent blindness

**Ocular Trauma**

**Blunt Trauma**

- caused by blunt object such as fist, squash ball
- history: injury, ocular history, drug allergy, tetanus status
- exam: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
- if VA normal or slightly reduced, globe less likely to be perforated
- if VA reduced may be perforated globe, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema
- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion – detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- retinal tear/detachment

**Penetrating Trauma**

- include ruptured globe ± prolapsed iris, intraocular foreign body
- rule out intraocular foreign body, especially if history of “metal striking metal”, orbit CT
- **OCULAR EMERGENCY**: initial management - REFER IMMEDIATELY
  - ABCs
  - don't press on eye globe!
  - don't check IOP if possibility of globe rupture
  - check vision, diplopia
  - apply rigid eye shield to minimize further trauma
  - keep head elevated 30-45° to keep IOP down
  - keep NPO
  - tetanus status
  - give IV antibiotics
  - selecting appropriate agents depends on the mechanism of injury; gram positive bacteria are more commonly involved than gram negatives; retained intraocular foreign objects increase the risk of infections with *Bacillus* species, whereas exposure to vegetable matter increased the risk of a fungal etiology

**Post-Traumatic Infectious Endophthalmitis**

- *Surv Ophthalmol* 2011;56:214-251
- Decreased VA
- Shallow anterior chamber
- Hyphema
- Abnormal pupil
- Ocular misalignment
- Retinal damage

**Management of Suspected Globe Rupture**

- CAN’T forget
  - **C**T orbits
  - **A**ncef (cefazolin) ± **A**minoglycoside IV
  - **N**PO
  - **T**etanus status

- Post-traumatic endophthalmitis in the absence of an intraocular foreign body (IOFB).
- If IOFB present, early vitrectomy and IOFB removal must be performed within 24 h of injury.
- Extreme pain with hypopyon and vitritis indicate endophthalmitis until proven otherwise, and samples must be obtained.
- Treat with empirical intravitreal and intravenous antibiotic guided by nature of trauma, and adjust based on culture.
Hyphema

• blood in anterior chamber often due to damage to root of the iris
• may occur with blunt trauma

Treatment

• refer to ophthalmology
  ▪ shield and bedrest for 5 d or as determined by ophthalmologist
  ▪ sleep with head upright
• may need surgical drainage if hyphema persists or if re-bleed

Complications

• risk of re-bleed highest on days 2-5, resulting in secondary glaucoma, corneal staining, and iris necrosis
• never prescribe Aspirin®, as it increases the risk of a re-bleed

Blow-Out Fracture

• see Plastic Surgery, PL32
• blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
• orbital rim remains intact
• inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
• infraorbital nerve courses along the floor of the orbit and may be damaged

Clinical Features

• pain and nausea at time of injury
• diplopia, restriction of EOM
• infraorbital and upper lip paresthesia (CN V2)
• enophthalmos (sunken eye), periorbital ecchymoses

Investigations

• plain films: Waters' view and lateral
• CT: anteroposterior and coronal view of orbits

Treatment

• refrain from coughing, blowing nose
• systemic antibiotics may be indicated
• surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
• may delay surgery if the diplopia improves

Chemical Burns

• alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
• poor prognosis if cornea opaque, likely irreversible stromal damage
• even with a clear cornea initially, alkali burns can progress for weeks (thus, very guarded prognosis)

Treatment

• immediately irrigate at site of accident with water or buffered solution
  ▪ IV drip for at least 20-30 min with eyelids retracted in emergency department
  ▪ swab upper and lower fornices to remove possible particulate matter
• do not attempt to neutralize because the heat produced by the reaction will damage the cornea
• cycloplegic drops to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
• topical antibiotics and patching
• topical steroids (by ophthalmologist) to decrease inflammation, use for <2 wk (in the case of a persistent epithelial defect)
**Surgical Ophthalmology**

- **dacrystorhinostomy (DCR):** excision of bone covering the nasolacrimal sac to restore tear drainage
- **blepharoplasty:** oculoplastic surgical correction of the eyelid by the excision and removal or repositioning of excess skin, fat, and/or the reinforcement of the corresponding muscle and tendon
- **LASIK (laser-assisted in situ keratomileusis):** a microkeratome is used to create a corneal flap followed by laser remodeling of the stroma to correct refractive error
- **trabeculectomy:** creation of a new outflow tract from anterior chamber to under conjunctiva; fibrosis prevented with mitomycin C or 5-FU injection during surgery
- **phacoemulsification (cataract extraction):** the use of ultrasonic waves to break up and aspirate a cataract followed by replacement with an artificial lens implant
- **femtosecond laser-assisted cataract surgery:** uses focused ultrashort pulses (10⁻¹⁵ of a second) to perform photodissection in achieving capsulorrhexis and lens fragmentation
- **vitrectomy:** the use of small gauge trochars to enter the posterior segment and remove vitreous; commonly used to treat vitreous hemorrhage and RD
- **pneumatic retinopexy:** intraocular injection of air or an expandable gas in order to tamponade a retinal break for repair of RD
- **scleral buckle:** a silicone band is secured on the outside of the globe that indents the eye wall, thereby relieving vitreous traction on the retina around any tears/holes and allowing the tears/holes to remain sealed for repair of RD
- **minimally invasive glaucoma surgery (MIGS):** implantation of IOP lowering drainage devices (e.g. iStent) through an ab interno microincisional approach during cataract surgery.

Common Medications

TOPICAL OCULAR DIAGNOSTIC DRUGS

**Fluorescein Dye**
- water soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope or slit-lamp)
- absorbed in areas of epithelial loss (ulcer or abrasion)
- also stains mucus and contact lenses

**Rose Bengal Stain**
- stains devitalized epithelial cells and mucus

Anesthetics
- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore **NEVER** prescribe

Mydriatics
- dilate pupils
- two classes
  - cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    - dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    - indications: refraction, ophthalmoscopy, therapy for iritis
  - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    - stimulate pupillary dilator muscles, no effect on accommodation
    - usually used with tropicamide for additive effects
    - side effects: HTN, tachycardia, arrhythmias

WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

VEGF Inhibitors
- block VEGF which prevents ocular angiogenesis and further development of choroidal neovascularization
- administered via intravitreal injections
- pegaptanib (Macugen®) is a selective anti-VEGF targeting VEGF isoform 165 (no longer widely used)
- ranibizumab (Lucentis®) is a non-selective anti-VEGF agent
- aflibercept (Eylea®) is an VEGF "trap" agent that binds VEGF-A and placental growth factor
- bevacizumab (Avastin®) is another non-selective anti-VEGF agent but is only FDA approved for metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its widespread ophthalmologic use is off-label

TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs
- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

Anti-Histamines
- used to relieve red and itchy eye, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes

Decongestants
- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine (Isoto Frin®)
- rebound vasodilation with overuse; rarely can precipitate angle closure glaucoma

Antibiotics
- indications: bacterial conjunctivitis, keratitis, or blepharitis
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin®), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan®], ofloxacin [Ocufox®], moxifloxacin [Vigamox®], gatifloxin [Zymar®])

Corticosteroids
- e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone (Predsol® 0.5%, Pred Forte® 1%), rimexolone (Vexol®), loteprednol etabonate 0.5% (Lotamax®), dexamethasone (Durezol®)
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
  - potentiates HSV keratitis and fungal keratitis as well as masks symptoms
  - increased IOP more rapidly in steroid responders (within weeks)
  - posterior subcapsular cataract (within months)

Fractures – General Principles

Fracture Description

1. Name of Injured Bone

2. Integrity of Skin/Soft Tissue
   - closed: skin/soft tissue over and near fracture is intact
   - open: skin/soft tissue over and near fracture is lacerated or abraded, fracture exposed to outside environment
     - signs: continuous bleeding from puncture site or fat droplets in blood are suggestive of an open fracture
3. Location
- epiphyseal: end of bone, forming part of the adjacent joint
- metaphyseal: the flared portion of the bone at the ends of the shaft
- diaphyseal: the shaft of a long bone (proximal, middle, distal)
- physis: growth plate

4. Orientation/Fracture Pattern
- transverse: fracture line perpendicular to long axis of bone; result of direct high energy force
- oblique: angular fracture line; result of angular or rotational force
- butterfly: fracture site fragment which looks like a butterfly
- segmental: a separate segment of bone bordered by fracture lines; result of high energy force
- spiral: complex, multi-planar fracture line; result of rotational force, low energy
- comminuted/multi-fragmentary: >2 fracture fragments
- intra-articular: fracture line crosses articular cartilage and enters joint
- avulsion: tendon or ligament tears/pulls off bone fragment; often in children, high energy
- compression/impacted: impaction of bone; typical sites are vertebrae or proximal tibia
- torus: a buckle fracture of one cortex, often in children
- greenstick: an incomplete fracture of one cortex, often in children
- pathologic: fracture through bone weakened by disease/tumour

5. Alignment of Fracture Fragments
- nondisplaced: fracture fragments are in anatomic alignment
- displaced: fracture fragments are not in anatomic alignment
- distracted: fracture fragments are separated by a gap (opposite of impacted)
- impacted: fracture fragments are compressed, resulting in shortened bone
- angulated: direction of fracture apex (e.g. varus/valgus)
- translated/shifted: percentage of overlapping bone at fracture site
- rotated: fracture fragment rotated about long axis of bone

Figure 4. Fracture types

Figure 5. Schematic diagram of the long bone

Approach to Fractures

1. Clinical Assessment
- ABCs, primary survey and secondary survey (ATLS protocol)
  - rule out other fractures/injuries
  - rule out open fracture
- AMPLE history (minimum): Allergies, Medications, Past medical history, Last meal, Events surrounding injury
  - mechanism of injury
  - previous significant injury or surgery to affected area
  - consider pathologic fracture with history of only minor trauma
- physical exam: look (deformity, soft tissue integrity); feel (maximal tenderness, NVS-document best possible neurovascular exam, avoid ROM/moving injured area to prevent exacerbation)

2. Analgesia
3. Imaging (see Orthopedic X-Ray Imaging, OR7)
4. Splint Extremity
5. Management: Closed vs. Open Reduction
   1. obtain the reduction (for appropriate IV sedation see Table 27, OR50)
      - closed reduction
        - apply traction in the long axis of the limb
        - reverse the mechanism that produced the fracture
        - reduce with IV sedation and muscle relaxation (fluoroscopy can be used if available)
• indications for open reduction
  ◦ “NO CAST”
  ◦ other indications include
    – failed closed reduction
    – not able to cast or apply traction due to site (e.g. hip fracture)
    – pathologic fractures
    – potential for improved function with ORIF
• ALWAYS re-check and document NVS after reduction and obtain post-reduction x-ray

2. maintain the reduction
• external stabilization: splints, casts, traction, external fixator
• internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixation (rods)
• follow-up: evaluate bone healing
3. rehabilitate to regain function and avoid joint stiffness

Fracture Healing

Normal Healing

Weeks 0-3  Hematoma, macrophages surround fracture site
Weeks 3-6  Osteoclasts remove sharp edges, callus forms within hematoma
Weeks 6-12  Bone forms within the callus, bridging fragments
Months 6-12  Cortical gap is bridged by bone
Years 1-2  Normal architecture is achieved through remodelling

Figure 7. Stages of bone healing

Evaluation of Healing: Tests of Union
• clinical: no longer tender to palpation or stressing on physical exam
• x-ray: trabeculae cross fracture site, visible callus bridging site on at least 3 of 4 cortices

Articular Cartilage

Properties
• 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
• avascular (nutrition from synovial fluid, aneural, alymphatic
• composed of: collagen (90% is type II; gives tensile strength), water, proteoglycans (gives compressive strength), and chondrocytes

ARTICULAR CARTILAGE DEFECTS

Etiology
• overt trauma, repetitive minor trauma (such as repetitive ankle sprains or patellar maltracking); common sports injury
• degenerative conditions such as early stage OA or osteochondritis dissecans

Indications for Open Reduction

NO CAST
Non-union
Open fracture
Neurovascular Compromise
Displaced intra-Articular fracture
Salter-Harris 3,4,5
PolyTrauma

Figure 6. Heterotopic ossification of femoral diaphysis after femur fracture and IM nailing

Wolff’s Law
Bone remodels itself to over time in response to mechanical load to better withstand loading stressors placed upon it

Heterotopic Ossification
The formation of bone in abnormal locations (e.g. in muscle), secondary to pathology

Avascular Necrosis
Ischemia of bone due to disrupted blood supply; commonly in bones covered by cartilage or with distal to proximal blood supply

Fracture Blister
Formation of vesicles or bullae that occur on edematous skin overlying a fractured bone
Clinical Features
- similar to symptoms of OA (joint line pain with possible effusion, etc.)
- often have predisposing factors, such as ligament injury, malalignment of the joint (varus/valgus), obesity, bone deficiency (AVN, osteochondritis dissecans, ganglion bone cysts), inflammatory arthropathy, and familial osteoarthropathy
- may have symptoms of locking or catching related to the torn/displaced cartilage

Investigations
- x-ray (to rule out bony defects and check alignment)
- MRI
- diagnostic arthroscopy (treatment is often guided by what is seen during arthroscopy)

Table 3. Outerbridge Classification of Chondral Defects

<table>
<thead>
<tr>
<th>Grade</th>
<th>Chondral Damage</th>

</tr>
<tr>
<td>III</td>
<td>Fragmentation and fissuring &gt;1/2’ in diameter</td>
</tr>
<tr>
<td>IV</td>
<td>Erosion of cartilage down to bone</td>
</tr>
</tbody>
</table>

Treatment
- individualized
  - patient factors (age, skeletal maturity, activity level, etc.)
  - defect factors (Outerbridge Classification, subchondral bone involvement, etc.)
- non-operative
  - rest, NSAIDs, bracing
- operative
  - microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

Orthopedic X-Ray Imaging

General Principles
- x-ray 1 joint above and 1 below
- obtain at least 2 orthogonal views ± specialized views

Orthopedic Emergencies

**Trauma Patient Workup**

**Etiology**
- high energy trauma e.g. MVC, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

**Clinical Features**
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension/hypovolemia
- consider involvement of EtOH or other substances

**Investigations**
- trauma survey (see Emergency Medicine, ER2, ER15)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- other views of pelvis: AP, inlet, and outlet: Judet views for acetabular fracture (for classification of pelvic fractures see Table 18, OR28)

**Treatment**
- ABCDEs and initiate resuscitation for life threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

**Complications**
- hemorrhage – life threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis if missed open fracture

**Open Fractures**
- fractured bone and hematoma in communication with the external environment

**Emergency Measures**
- ABCs, primary survey and resuscitation as needed
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated

33% of patients with open fractures have multiple injuries
• cover wound with sterile dressings
• immediate IV antibiotics
• tetanus toxoid or immunoglobulin as needed
• reduce and splint fracture
• NPO and prepare for OR (blood work, consent, ECG, CXR)
  • operative irrigation and debridement within 6-8 h to decrease risk of infection
  • traumatic wound often left open to drain but vacuum-assisted closure dressing may be used
  • re-examine with repeat irrigation and debridement in 48 h

Table 5. Gustilo Classification of Open Fractures

<table>
<thead>
<tr>
<th>Gustilo Grade</th>
<th>Length of Open Wound</th>
<th>Description</th>
<th>Prophylactic Antibiotic Regimen</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>&lt;1 cm</td>
<td>Minimal contamination and soft tissue injury Simple or minimally comminuted fracture</td>
<td>First generation cephalosporin (cefazolin) for 3 d If allergy use fluoroquinolone If MRSA positive use vancomycin</td>
</tr>
<tr>
<td>II</td>
<td>1-10 cm</td>
<td>Moderate contamination Moderate soft tissue injury</td>
<td>As per Grade I</td>
</tr>
<tr>
<td>III*</td>
<td>&gt;10 cm</td>
<td>IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound IIIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound IIIC: Vascular injury/compromise</td>
<td>First generation cephalosporin (cefazolin) for 3 d plus Gram-negative coverage (gentamicin) for at least 3 d For soil contamination, penicillin is added for clostridial coverage</td>
</tr>
</tbody>
</table>

*Any high energy, comminuted fracture, shot gun, farmyard/tail/water contamination, exposure to oral flora, or fracture >8 h old is immediately classified as Grade III

Cauda Equina Syndrome

• see Neurosurgery, NS26

Compartment Syndrome

Definition
• increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment) with little room for expansion
• interstitial pressure exceeds capillary perfusion pressure leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

Etiology
• intracompartmental: fracture (particularly tibial shaft fractures, pediatric supracondylar fractures, and forearm fractures), reperfusion injury, crush injury, ischemia
• extracompartmental: constrictive dressing (circumferential cast, poor positioning during surgery), circumferential burn

![Figure 8. Pathogenesis of compartment syndrome](image)

Clinical Features
• pain out of proportion to injury (typically first symptom)
• pain with active contraction of compartment
• pain with passive stretch (most sensitive)
• swollen, tense compartment
• suspicious history

• 5 Ps: late sign – do not wait for these to develop to make the diagnosis!
Investigations
• usually not necessary as compartment syndrome is a clinical diagnosis
• in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter AFTER clinical diagnosis is made (normal = 0 mmHg; elevated ≥30 mmHg or [measured pressure – dBP] ≤30 mmHg)

Treatment
• non-operative
  • remove constrictive dressings (casts, splints), elevate limb at the level of the heart
• operative
  • urgent fasciotomy
  • 48-72 h post-operative: wound closure ± necrotic tissue debridement

Complications
• Volkmann’s ischemic contracture: ischemic necrosis of muscle, followed by secondary fibrosis and finally calcification; especially following supracondylar fracture of humerus
• rhabdomyolysis, renal failure secondary to myoglobinuria

Osteomyelitis

• bone infection with progressive inflammatory destruction

Etiology
• most commonly caused by Staphylococcus aureus
• mechanism of spread: hematogenous (most common) vs. direct-inoculation vs. contiguous focus
• risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

Clinical Features
• symptoms: pain and fever
• on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

Diagnosis
• see Medical Imaging, MI24
• workup includes: WBC and diff, ESR, CRP, blood culture, aspirate culture/bone biopsy

Table 6. Treatment of Osteomyelitis

<table>
<thead>
<tr>
<th>Acute Osteomyelitis</th>
<th>Chronic Osteomyelitis</th>
</tr>
</thead>
<tbody>
<tr>
<td>IV antibiotics 4-6 wk; started empirically and adjusted after obtaining blood and aspirate cultures ± surgery (IBG) for abscess or significant involvement ± hardware removal if present</td>
<td>Surgical debridement Antibiotics: both local (e.g. antibiotic beads) and systemic (IV)</td>
</tr>
</tbody>
</table>

Septic Joint

• joint infection with progressive destruction if left untreated
• risk factors: young/elderly (age >80 yr), RA, prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, previous intra-articular corticosteroid injection, immune compromise (cancer, DM, alcoholism)

Etiology
• most commonly caused by Staphylococcus aureus in adults
• consider coagulase-negative Staphylococcus in patients with prior joint replacement
• consider Neisseria gonorrhoeae in sexually active adults and newborns
• most common route of infection is hematogenous

Clinical Features
• inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

Investigations
• x-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
• joint aspirate: cloudy yellow fluid, WBC >50,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level <60% blood glucose level, no crystals, positive Gram stain results
• listen for heart murmur (to reduce suspicion of infective endocarditis, use Duke Criteria)

Rapid progression of signs and symptoms (over hours) necessitates need for serial examinations
Plain Film Findings in a Septic Joint
• Early (0-3 d): usually normal; may show soft-tissue swelling or joint space widening from localized edema
• Late (4-6 d): joint space narrowing and destruction of cartilage

Serial C-reactive protein (CRP) can be used to monitor response to therapy
**Shoulder Dislocation**

- **Treatment**
  - IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
  - non-operative
    - therapeutic joint aspiration, serially if necessary (if early diagnosis and joint superficial)
    - operative
    - arthroscopic/open irrigation and irrigation and drainage ± decompression

**Shoulder**

**Shoulder Dislocation**

- complete separation of the glenohumeral joint; may be anterior or posterior

**Investigations**

- anterior dislocation x-rays (AP, trans-scapular, axillary views)
- posterior dislocation x-rays (AP, trans-scapular, axillary) or CT scan

**Table 7. Anterior and Posterior Shoulder Dislocation**

<table>
<thead>

Prognosis
- recurrence rate depends on age of first dislocation
  - <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

Specific Complications
- rotator cuff or capsular or labral tear (Bankart/SLAP lesion), shoulder stiffness
- injury to axillary nerve/artery, brachial plexus
- recurrent/unreduced dislocation (most common complication)

![Figure 11. Posterior view of anterior dislocation causing Hill-Sachs and Bankart lesions](image1)

Figure 12. Shoulder maneuvers

Rotator Cuff Disease
- rotator cuff consists of 4 muscles that act to stabilize humeral head within the glenoid fossa

Factors Causing Shoulder Instability
- Shallow glenoid
- Loose capsule
- Ligamentous laxity

Frequency of Dislocations
- Anterior shoulder > Posterior shoulder
- Posterior hip > Anterior hip

The glenohumeral joint is the most commonly dislocated joint in the body since stability is sacrificed for motion.
SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

Etiology
- outlet/subacromial impingement: “painful arc syndrome”, compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint, and CA ligament
  - leads to bursitis, tendonitis, and if left untreated, can lead to rotator cuff thinning and tear
  - anything that leads to a narrow subacromial space
  - glenohumeral muscle weakness leading to abnormal motion of humeral head
  - scapular muscle weakness leading to abnormal motion of acromion
  - acromial abnormalities such as congenital narrow space or osteophyte formation or Type III acromion morphology

Clinical Features
- insidious onset, but may present as an acute exacerbation of chronic disease, night pain and difficulty sleeping on affected side
- pain worse with active motion (especially overhead); passive movement generally permitted
- weakness and loss of ROM especially between 90°-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed and Yergason’s tests; SLAP lesion: O’Brien’s test

Investigations
- x-ray: AP view may show high riding humerus relative to glenoid indicating large tear, evidence of chronic tendonitis
- MRI: coronal/sagittal oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: can assess full thickness tears, difficult to assess partial tears

Treatment
- non-operative
  - physiotherapy, NSAIDs ± steroid injection
  - for mild (“wear”) or moderate (“tear”) cases
- operative
  - indication: severe (“repair”)
    - impingement that is refractory to 2-3 mo physiotherapy and 1-2 corticosteroid injections
    - arthroscopic or open surgical repair (ie. acromioplasty, rotator cuff repair)

Results/Conclusions: Among pain provocation tests, a positive painful arc test had the greatest specificity and sensitivity (SP 81%, SN 71%).

Does this Patient with Shoulder Pain have Rotator Cuff Disease? The Rational Clinical Examination Systematic Review
- Study: 5 studies of sufficient quality including 30-203 shoulders and a prevalence of RCD ranging from 33-81%.

Screening Out Rotator Cuff Tears
- No night pain (SN 87.7%)
- No painful arc (SN 97.5%)
- No impingement signs (SN 97.2%)
- No weakness

Returning to the bedside: Using the history and physical examination to identify rotator cuff tears

  - Infraspinatus
  - Teres minor
  - Subscapularis

Ruling in Rotator Cuff Tears – 98% probability of rotator cuff tear if all 3 of the following are present:
- Supraspinatus weakness
- External rotation weakness
- Positive impingement sign(s)

Diagnosis of rotator cuff tears. Lancet 2001; 357:769-770
Acromioclavicular Joint Pathology

- subluxation or dislocation of AC joint
- 2 main ligaments attach clavicle to scapula: AC and CC ligaments

Mechanism
- fall onto shoulder with adducted arm or direct trauma to point of shoulder

Clinical Features
- pain with adduction of shoulder and/or palpation over AC joint
- palpate step deformity between distal clavicle and acromion (with dislocation)
- limited ROM

Investigations
- x-rays: bilateral AP, Zanca view (10-15° cephalic tilt), axillary

Treatment
- non-operative
  - sling 1-3 wk, ice, analgesia, early ROM and rehabilitation
- operative
  - indication: Rockwood Class IV-VI (III if labourer or high level athlete)
  - number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

Pneumothorax or pulmonary contusion are potential complications of severe AC joint dislocation
**Table 10. Rockwood Classification of Acromioclavicular Joint Separation**

**Clavicle Fracture**

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

**Mechanism**
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

**Clinical Features**
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

**Investigations**
- evaluate NVS of entire upper limb
- x-ray: AP, 45° cephalic tilt (superior/inferior displacement), 45° caudal tilt (AP displacement)
- CT: useful for medial physeal fractures and sternoclavicular injury

**Treatment**
- medial and middle third clavicle fractures
  - figure-of-eight sling x 1-2 wk
  - early ROM and strengthening once pain subsides
  - if ends overlap >2 cm consider ORIF
- distal third clavicle fractures
  - undisplaced (with ligaments intact): sling x 1-2 wk
  - displaced (CC ligament injury): ORIF

**Specific Complications** (see General Fracture Complications, OR6)
- cosmetic bump usually only complication
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)

**Frozen Shoulder (Adhesive Capsulitis)**

- disorder characterized by progressive pain and stiffness of the shoulder usually resolving spontaneously after 18 mo

**Mechanism**
- primary adhesive capsulitis
  - idiopathic, usually associated with DM
  - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
  - due to prolonged immobilization
  - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
  - following MI, stroke, shoulder trauma
  - poorer outcomes

**Clinical Features**
- gradual onset (weeks to months) of diffuse shoulder pain with:
  - decreased active AND passive ROM
  - pain worse at night and often prevents sleeping on affected side
  - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

**Investigations**
- x-ray: AP (neutral, internal/external rotation), scapular Y, axillary
  - may be normal, or may show demineralization from disease
**Humerus**

## Proximal Humeral Fracture

### Mechanism
- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

### Clinical Features
- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm and chest

### Investigations
- test axillary nerve function (deltoid contraction and skin over deltoid)
- x-rays: AP, trans-scapular, axillary are essential
- CT scan: to evaluate for articular involvement and fracture displacement

### Classification
- Neer classification is based on 4 fracture fragments
- displaced: displacement >1 cm and/or angulation >45°
- the Neer system regards displacement, not the fracture line, as meeting criteria for a ‘part’ in the classification scheme
- ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

### Treatment
- treat osteoporosis if needed
- non-operative
  - nondisplaced: broad arm sling immobilization, begin ROM within 14 d to prevent stiffness
  - minimally displaced (85% of patients) - closed reduction with sling immobilization x 2 wk, gentle ROM
- operative
  - ORIF (anatomic neck fractures, displaced, associated dislocated glenohumeral joint)
  - hemiarthroplasty may be necessary, especially in elderly

### Specific Complications (see General Fracture Complications, OR6)
- AVN, nerve palsy (45% typically axillary nerve), malunion, post-traumatic arthritis

## Humeral Shaft Fracture

### Mechanism
- high energy: direct blows/MVC (especially young); low energy: FOOSH, twisting injuries, metastases (in elderly)

### Clinical Features
- pain, swelling, weakness ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment dorsum of hand

### Investigations
- x-ray: AP and lateral radiographs of the humerus including the shoulder and elbow joints

### Treatment
- in general, humeral shaft fractures are treated non-operatively
- non-operative
  - ± reduction; can accept deformity due to compensatory ROM of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: open fracture, neurovascular injury, unacceptable fracture alignment, polytrauma, segmental fracture, pathological fracture, “floating elbow” (simultaneous unstable humeral and forearm fractures), intra-articular
  - ORIF: plating (most common), IM rod insertion, external fixation

---

![Figure 15. Fractures of the proximal humerus](https://via.placeholder.com/150)

**Acceptable Humeral Shaft Deformities for Non-Operative Treatment**
- <20° anterior angulation
- <30° varus angulation
- <3 cm of shortening
Specific Complications (see General Fracture Complications, OR6)
• radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
• non-union: most frequently seen in middle 1/3
• decreased ROM
• compartment syndrome

Distal Humeral Fracture

Mechanism
• young: high energy trauma (MVC)
• elderly: FOOSH

Clinical Features
• elbow pain and swelling
• assess brachial artery

Investigations
• x-ray: AP and lateral of humerus and elbow
• CT scan: helpful when suspect shear fracture of capitulum or trochlea

Classification
• supracondylar, distal single column, distal bicolumnar and coronal shear fractures

Treatment
• goal is to restore ROM 30-130° flexion (unsatisfactory outcomes in 25%)
• non-operative
  ▪ cast immobilization (in supination for lateral condyle fracture; pronation for medial condyle fractures)
• operative
  ▪ indications: displaced, supracondylar, bicolumnar
  ▪ closed reduction and percutaneous pinning; ORIF; total elbow arthroplasty (bicolumnar in elderly)

Elbow

Supracondylar Fracture

• subclass of distal humerus fracture: extra-articular, fracture proximal to capitulum and trochlea, usually transverse
• most common in pediatric population (peak age ~7 yr old), rarely seen in adults
• AIN injury commonly associated with extension type

Mechanism
• >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

Clinical Features
• pain, swelling, point tenderness
• neurovascular injury: assess median and radial nerves, radial artery (check radial pulse)

Investigations
• x-ray: AP, lateral of elbow
  ▪ disruption of anterior humeral line suggests supracondylar fracture

Treatment
• reduction indications: evidence of arterial obstruction, unacceptable angulation, displaced (>50%)
• non-operative
  ▪ nondisplaced: long arm plaster slab in 90° flexion x 3 wk
• operative
  ▪ indications: displaced, vascular injury, open fracture
  ▪ requires percutaneous pinning followed by limb cast with elbow flexed <90°
  ▪ in adults, ORIF is necessary

Specific Complications (see General Fracture Complications, OR6)
• stiffness is most common
• brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann’s ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

Three Joints at the Elbow
• Humeroradial joint
• Humeroulnar joint
• Radioulnar joint

Figure 16. X-ray of transverse displaced supracondylar fracture of humerus with elbow dislocation

Normal carrying angle of elbow is ~10° of valgus

Terrible Triad
• Radial head fracture
• Coronoid fracture
• Elbow dislocation

Figure 17. X-ray of fat pad sign
Radial Head Fracture

- a common fracture of the upper limb in young adults

Mechanism
- FOOSH with elbow extended and forearm pronated

Clinical Features
- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, ± mechanical block to forearm pronation and supination
- pain on pronation/supination

Investigations
- x-ray: enlarged anterior fat pad ("sail sign") or the presence of a posterior fat pad indicates effusion which could occur with occult radial head fractures

Table 11. Classification and Treatment of Radial Head Fractures

</tr>
<tr>
<td>4</td>
<td>Comminuted fracture with posterior elbow dislocation</td>
<td>Radial head excision ± prosthesis</td>
</tr>
</tbody>
</table>

Specific Complications (see General Fracture Complications, OR6)
- myositis ossificans – calcification of muscle
- recurrent instability (if MCL injured and radial head excised)

Olecranon Fracture

Mechanism
- direct trauma to posterior aspect of elbow (fall onto the point of the elbow) or FOOSH

Clinical Features
- localized pain, palpable defect
- ± loss of active extension due to avulsion of triceps tendon

Investigations
- x-ray: AP and lateral (require true lateral to determine fracture pattern)

Treatment
- non-operative
  - non-displaced (<2 mm, stable): cast x 3 wk (elbow in 90° flexion) then gentle ROM
- operative
  - displaced: ORIF (plate and screws or tension band wiring) and early ROM if stable

Elbow Dislocation

- third most common joint dislocation after shoulder and patella
- anterior capsule and collateral ligaments disrupted

Mechanism
- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
- usually the radius and ulna are dislocated together, or the radius head dislocates and the ulna remains ("Monteggia")
- 80% are posterior/posterolateral, anterior are rare and usually devastating

Clinical Features
- elbow pain, swelling, deformity
- flexion contracture
- ± absent radial or ulnar pulses

Investigations
- x-ray: AP and lateral views

Treatment
- assess NVS before reduction: brachial artery, median and ulnar nerves (can become entrapped during manipulation)
• non-operative
  ▪ closed reduction under conscious sedation (post-reduction x-rays required)
  ▪ Parvin’s method: patient lies prone with arm hanging down; apply gentle traction downwards
    on wrist, as olecranon slips distally, gently lift up the arm at elbow to reduce joint
  ▪ long-arm splint with forearm in neutral rotation and elbow in 90° flexion
  ▪ early ROM (<2 wk)
• operative
  ▪ indications: complex dislocation or persistent instability after closed reduction
  ▪ ORIF

Specific Complications (see General Fracture Complications, OR6)
• stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
• recurrent instability uncommon

Epicondylitis

• lateral epicondylitis = “tennis elbow”, inflammation of the common extensor tendon as it inserts into the lateral epicondyle
• medial epicondylitis = “golfer’s elbow”, inflammation of the common flexor tendon as it inserts into the medial epicondyle

Mechanism
• repeated or sustained contraction of the forearm muscles/chronic overuse

Clinical Features
• point tenderness over humeral epicondyle and/or distal to it
• pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
• generally a self-limited condition, but may take 6-18 mo to resolve

Treatment
• non-operative (very good outcomes)
  ▪ rest, ice, NSAIDs
  ▪ use brace/strap
  ▪ physiotherapy, stretching, and strengthening
  ▪ corticosteroid injection
• operative
  ▪ indication: failed 6-12 mo conservative therapy
  ▪ percutaneous or open release of common tendon from epicondyle

Forearm

Radius and Ulna Shaft Fractures

Mechanism
• high energy direct or indirect (MVA, fall from height, sports) trauma
• fractures usually accompanied by displacement due to high force

Clinical Features
• deformity, pain, swelling
• loss of function in hand and forearm

Investigations
• x-ray: AP and lateral of forearm ± oblique of elbow and wrist
• CT if fracture is close to joint

Treatment
• goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
• ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

Complications (see General Fracture Complications, OR6)
• soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted
**Monteggia Fracture**

- more common and better prognosis in the pediatric age group when compared to adults
- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury

**Mechanism**
- direct blow on the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

**Clinical Features**
- pain, swelling, decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

**Investigations**
- x-ray: AP, lateral elbow, wrist and forearm

**Treatment**
- adults: ORIF of ulna with indirect radius reduction in 90% of patients (ORIF of radius if unsuccessful)
- splint and early post-operative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 6 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

**Specific Complications** (see General Fracture Complications, OR6)
- PIN: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis

**Nightstick Fracture**

- isolated fracture of ulna without dislocation of radial head

**Mechanism**
- direct blow to forearm (e.g. holding arm up to protect face)

**Treatment**
- non-operative
  - non-displaced
  - below elbow cast (x 10 d) followed by forearm brace (~8 wk)
  - operative
    - displaced
    - ORIF if >50% shaft displacement or >10° angulation

**Galeazzi Fracture**

- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis
- 3x more common than Monteggia fracture

**Mechanism**
- hand FOOSH with axial loading of pronated forearm or direct wrist trauma

**Clinical Features**
- pain, swelling, deformity and point tenderness at fracture site

**Investigations**
- x-ray: AP, lateral elbow, wrist and forearm
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

**Treatment**
- all cases are operative
  - ORIF of radius; afterwards assess DRUJ stability by balloting distal ulna relative to distal radius
    - if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
    - if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 6 wk

---

**Bado Type Classification of Monteggia Fractures**

Based on the direction of displacement of the dislocated radial head, generally the same direction as the apex of the ulnar fracture

- Type I: anterior dislocation of radial head and proximal/middle third ulnar fracture (60%)
- Type II: posterior dislocation of radial head and proximal/middle third ulnar fracture (15%)
- Type III: lateral dislocation of radial head and metaphyseal ulnar fracture (20%)
- Type IV – combined: proximal fracture of the ulna and radius, dislocation of the radial head in any direction (<5%)

---

For all isolated radius fractures assess DRUJ to rule out a Galeazzi fracture
Wrist

Colles’ Fracture

• extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture
• most common fracture in those >40 yr, especially in women and those with osteoporotic bone

Mechanism
• FOOSH

Clinical Features
• “dinner fork” deformity
• swelling, ecchymoses, tenderness

Investigations
• x-ray: AP and lateral wrist

Treatment
• goal is to restore radial height (13 mm), radial inclination (22°), volar tilt (11°) as well as DRUJ stability and useful forearm rotation
• non-operative
  • closed reduction (think opposite of the deformity)
    • hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
    • closed reduction: 1) traction with extension (exaggerate injury), 2) traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
    • dorsal slab/below elbow cast for 5-6 wk
    • x-ray x 1 wk for 3 wk and at cessation of immobilization to ensure reduction is maintained
  • obtain post-reduction films immediately; repeat reduction if necessary
• operative
  • indication: failed closed reduction, or loss of reduction
  • percutaneous pinning, external fixation or ORIF

Smith’s Fracture

• volar displacement of the distal radius (i.e. reverse Colles’ fracture)

Mechanism
• fall onto the back of the flexed hand

Investigations
• x-ray: AP and lateral wrist

Treatment
• usually unstable and needs ORIF
• if patient is poor operative candidate, may attempt non-operative treatment
  • closed reduction with hematoma block (reduction opposite of Colles’)
  • long-arm cast in supination x 6 wk

Complications of Wrist Fractures

• most common complications are poor grip strength, stiffness, and radial shortening
• distal radius fractures in individuals <40 yr of age are usually highly comminuted and are likely to require ORIF
• 80% have normal function in 6-12 mo

- Figure 23. Normal wrist angles + wrist angles in Colles’ fracture
- Table 12. Early and Late Complications of Wrist Fractures
- Indications for surgical management of Colles’ fracture
Scaphoid Fracture

Epidemiology
- common in young men; not common in children or in patients beyond middle age
- most common carpal bone injured
- may be associated with other carpal or wrist injuries (e.g. Colles' fracture)

Mechanism
- FOOSH: impact of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), distal (10%), or proximal (25%) scaphoid

Clinical Features
- pain with resisted pronation
- tenderness in the anatomical "snuff box", over scaphoid tubercle, and pain with long axis compression into scaphoid
- usually nondisplaced

Investigations
- x-ray: AP, lateral, scaphoid views with wrist extension and ulnar deviation
- ± CT or MRI
- bone scan rarely used
- note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative order CT or MRI

Treatment
- early treatment critical for improving outcomes
- non-operative
  - non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk then short arm cast until radiographic evidence of healing is seen (2-3 mo)
- operative
  - displaced: ORIF with headless/countersink compression screw is the mainstay treatment

Specific Complications (see General Fracture Complications, OR6)
- most common: non-union/mal-union (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)
- scaphoid nonunion advanced collapse (SNAC) – chronic nonunion leading to advanced collapse and arthritis of wrist

Prognosis
- proximal fifth fracture: AVN rate 100%; proximal third fracture: AVN rate 33%
- waist fractures have healing rates of 80-90%
- distal third fractures have healing rates close to 100%

**Cervical Spine**

**General Principles**
- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

**Special Testing**
- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain

**Table 13. Cervical Radiculopathy/Neuropathy**

**X-Rays for C-Spine**
- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
  - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - angulation: between adjacent vertebral bodies (>11° is abnormal)
  - disc or facet joint widening
  - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae
Differential Diagnosis of C-Spine Pain
- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome

C-SPINE INJURY
- see Neurosurgery, NS33

Thoracolumbar Spine

General Principles
- spinal cord terminates at conus medullaris (L1)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

Special Tests
- straight leg raise: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- Lasegue maneuver: dorsiflexion of foot during straight leg raise makes symptoms worse or, if leg is less elevated, dorsiflexion will bring on symptoms
- femoral stretch test: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in anterior thigh

*Unreliable

Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - peripheral nerve compression (disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
   - cauda equina syndrome
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)

DEGENERATIVE DISC DISEASE
- loss of vertebral disc height with age results in
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation

Mechanism
- compression over time with age

Clinical Features
- axial back pain without radicular symptoms
- pain worse with axial loading and bending
- negative straight leg raise

ABC'S Approach to the Lateral C-Spine X-Ray
A – Alignment/angulation
B – Bony Deformity
C – Cartilage
S – Soft Tissue

C-Spine X-Ray in Trauma
Must see C7-T1

All trauma patients with suspected C-spine injury require immediate immobilization of C-spine at scene of accident with spine board, C-collar, and sandbags
Investigations
• X-ray, MRI, provocative discography

Treatment
• non-operative
  ▪ staying active with modified activity
  ▪ back strengthening
  ▪ NSAIDs
  ▪ do not treat with opioids; no proven efficacy of spinal traction or manipulation
• operative – rarely indicated
  ▪ decompression ± fusion
  ▪ no difference in outcome between non-operative and surgical management at 2 yr

SPINAL STENOSIS
• narrowing of spinal canal <10 mm
• congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylitis, Paget’s disease, trauma)

Clinical Features
• ± bilateral back and leg pain
• neurogenic claudication
• ± motor weakness
• normal back flexion; difficulty with back extension (Kemp sign)
• positive Straight leg raise, pain not worse with Valsalva

Investigations
• CT/MRI reveals narrowing of spinal canal, but gold standard = CT myelogram

Treatment
• non-operative
  ▪ vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
• operative
  ▪ indication: non-operative failure >6 mo
  ▪ decompressive surgery

MECHANICAL BACK PAIN
• back pain NOT due to prolapsed disc or any other clearly defined pathology

Clinical Features
• dull backache aggravated by activity and prolonged standing
• morning stiffness
• no neurological signs

Treatment
• symptomatic (analgesics, physiotherapy)
• prognosis: symptoms may resolve in 4-6 wk, others become chronic

LUMBAR DISC HERNIATION
• tear in annulus fibrosus allows protrusion of nucleus pulposus causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
• 3:1 male to female
• only 5% become symptomatic
• usually a history of flexion-type injury

Clinical Features
• back dominant pain (central herniation) or leg dominant pain (lateral herniation)
• tenderness between spinous processes at affected level
• muscle spasm ± loss of normal lumbar lordosis
• neurological disturbance is segmental and varies with level of central herniation
  ▪ motor weakness (L4, L5, S1)
  ▪ diminished reflexes (L4, S1)
  ▪ diminished sensation (L4, L5, S1)
• positive straight leg raise
• positive contralateral SLR
• positive Laségue and Bowstring sign
• cauda equina syndrome (present in 1-10%) – surgical emergency

Investigations
• x-ray, MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome

Treatment
• non-operative
  ▪ symptomatic
    • extension protocol
    • NSAIDS
• operative
  ▪ indication: progressive neurological deficit, failure of symptoms to resolve within 3 mo or cauda equina syndrome due to central disc herniation
  ▪ surgical discectomy
• prognosis
  • 90% of patients improve in 3 mo with non-operative treatment

SPONDYLOLYSIS
• defect in the pars interarticularis with no movement of the vertebral bodies

Mechanism
trauma: gymnasts, weightlifters, backpackers, loggers, labourers

Clinical Features
activity-related back pain, pain with unilateral extension (Michelis' test)
**Investigations**
- oblique x-ray: “collar” break in the “Scottie dog’s” neck
- bone scan
- CT scan

**Treatment**
- non-operative
  - activity restriction, brace, stretching exercise

**ADULT ISTHMIC SPONDYLOLISTHESIS**
- defect in pars interarticularis causing a forward slip of one vertebra on another usually at L5-S1, less commonly at L4-5

**Mechanism**
- congenital (children), degenerative (adults), traumatic, pathological, teratogenic

**Clinical Features**
- lower back pain radiating to buttocks relieved with sitting
- neurogenic claudication
- L5 radiculopathy
- Meyerding Classification (percentage of slip)

**Investigations**
- x-ray (AP, lateral, obliques flexion-extension views), MRI

**Treatment**
- non-operative
  - activity restriction, bracing, NSAIDS
- operative
  - see Table 17

</table>

**Specific Complications**
- may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

---

**Pelvis**

**Pelvic Fracture**

**Mechanism**
- young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- elderly: fall from standing height, low energy trauma
- lateral compression, vertical shear, or anteroposterior compression fractures

**Clinical Features**
- pain, inability to bear weight
- local swelling, tenderness
- deformity of lower extremity
- pelvic instability

**Investigations**
- x-ray: AP pelvis, inlet and outlet views, Judet views (obturator and iliac oblique for acetabular fracture)
  - 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, tear drop, roof, posterior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - if involved, the fracture is considered an open fracture

---

Possible Radiological Findings
- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (iliopectineal line) or posterior column (ilioischial line)
- “Teardrop” displacement: acetabular fracture
- Iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)
Classification

</tr>
<tr>
<td></td>
<td></td>
<td>C3: bilateral both sides type C</td>
</tr>
</tbody>
</table>

Treatment

- ABCDEs
- non-operative treatment: protected weight bearing
  - indication: stable fracture
- emergency management
  - IV fluids/blood
  - pelvic binder/sheeting
  - external fixation vs. emergent angiography/embolization
  - ± laparotomy (if FAST/DPL positive)
- operative treatment: ORIF
  - indications:
    - unstable pelvic ring injury
    - disruption of anterior and posterior SI ligament
    - symphysis diastasis >2.5 cm
    - vertical instability of the posterior pelvis
    - open fracture

Complications (see General Fracture Complications, OR6)

- hemorrhage (life-threatening)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

Hip

Hip Dislocation

- full trauma survey (see Emergency Medicine, Initial Patient Assessment/Management, ER2)
- examine for neurovascular injury PRIOR to open or closed reduction
- reduce hip dislocations ASAP (ideally within 6 h) to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see Hip Dislocation Post-Total Hip Arthroplasty, OR30

ANTERIOR HIP DISLOCATION

- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

POSTERIOR HIP DISLOCATION

- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
  - e.g. knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb
- treatment

Figure 33. Illustration of the Tile classification of pelvic fractures

Figure 34. Rochester method
closed reduction under conscious sedation/GA only if no associated femoral neck fracture or ipsilateral displacement
• ORIF if unstable, intra-articular fragments or posterior wall fracture
• post-reduction CT to assess joint congruity and fractures
• if reduction is unstable, put in traction x 4-6 wk

CENTRAL HIP FRACTURE DISLOCATION
• traumatic injury where femoral head is pushed medially through acetabulum

COMPLICATIONS FOR ALL HIP DISLOCATIONS
• post-traumatic OA
• AVN of femoral head
• fracture of femoral head, neck, or shaft
• sciatic nerve palsy in 25% (10% permanent)
• HO
• thromboembolism – DVT/PE

Hip Fracture

General Features
• acute onset of hip pain
• unable to weight-bear
• shortened and externally rotated leg
• painful ROM

Table 19. Overview of Hip Fractures

Arthritis of the Hip

Etiology
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

Clinical Features
- pain (groin, medial thigh) and stiffness aggravated by activity, better with rest in OA
- RA: morning stiffness >1 h, multiple joint swelling, hand nodules
- decreased ROM (internal rotation is lost first)
- crepitus
- effusion
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenburg sign

Investigations
- x-ray: weight bearing views of affected joint
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - RA: osteopenia, erosion, joint space narrowing, subchondral cysts, symmetric joint space narrowing
- blood work: ANA, RF

Treatment
- non-operative
  - weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative
  - indication: advanced disease
  - realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
  - complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
  - arthroplasty is standard of care in most patients with hip arthritis

Hip Dislocation Post-Total Hip Arthroplasty

- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

Mechanism
- THA that is unstable when hip is flexed, adducted and internally rotated, or extended and externally rotated (avoid flexing hip >90° or crossing legs for ~6 wk after surgery)

Investigations
- x-ray: AP pelvis, AP and lateral hip

Treatment
- non-operative
  - closed reduction: external abduction splint to prevent hip adduction (most often)
- operative
  - indication: 2 or more dislocations with evidence of polyethylene wear, malalignment, hardware failure
    - revision THA
    - conversion to hemiarthroplasty with a larger femoral head
    - resection arthroplasty is a last resort

Complications
- sciatic nerve palsy in 25% (10% permanent)
- HO
- infection
Femur

Femoral Diaphysis Fracture

Mechanism
• high energy trauma (MVC, fall from height, gunshot wound)
• in children, can result from low energy trauma (spiral fracture)

Clinical Features
• shortened, externally rotated leg (if fracture displaced)
• inability to weight-bear
• often open injury, always a Gustilo III (see Table 5, OR9)
• Winquist and Hansen classification

Investigations
• x-ray: AP pelvis, AP/lateral hip, femur, knee

Treatment
• stabilize patient
• non-operative (uncommon)
  ▪ indication: non-displaced femoral shaft fractures in co-morbid patients
  ▪ long leg cast
• operative
  ▪ ORIF with anterograde IM nail (most common) or retrograde IM nail, external fixator for unstable patients, open fractures, or highly vascular areas, or plate and screws for open growth plates within 24 h
  ▪ early mobilization and strengthening

Complications
• hemorrhage requiring transfusion
• fat embolism leading to ARDS
• extensive soft tissue damage
• ipsilateral hip dislocation/fracture (2-6%)
• nerve injury

Distal Femoral Fracture

• fractures from articular surface to 5cm above metaphyseal flare

Mechanism
• direct high energy force or axial loading
• three types: extra articular, partial articular, complete articular

Clinical Features
• extreme pain
• knee effusion (hemarthrosis)
• shortened, externally rotated leg if displaced
• neurovascular deficits can occur with displaced fracture

Investigations
• x-ray: AP, lateral, traction views (AP, lateral, oblique,
• CT, angiography if diminished pulses

Treatment
• non-operative (uncommon)
  ▪ indication: non-displaced fracture
  ▪ hinged knee brace
• operative
  ▪ indication: displaced fracture, intra-articular fracture, non-union
  ▪ ORIF or retrograde IM nail if supracondylar and non-comminuted
  ▪ early mobilization and strengthening

Complications (see General Fracture Complications, OR6)
• femoral artery tear
• popliteal artery injury
• nerve injury
• extensive soft tissue injury
• angulation deformities
Knee

Evaluation of Knee

Common Complaints

- general orthopedic history
- also inquire about common knee symptoms
  - locking: mechanical block to extension
  - effusion, muscle spasm after injury, arthritis
  - painful clicking (audible)
  - torn meniscus
  - giving way; instability
  - cruciate ligament or meniscal tear, patellar dislocation

Special Tests of the Knee

- anterior and posterior drawer tests
  - demonstrate ACL and PCL, respectively
  - if able to sublux tibia anteriorly (anterior drawer test), then ACL may be torn
  - if able to sublux tibia posteriorly (posterior drawer test), then PCL may be torn
  - anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio

- Lachmann test
  - demonstrates torn ACL
  - hold knee in 10-20° flexion, stabilizing the femur
  - try to sublux tibia anteriorly on femur
  - similar to anterior drawer test, more reliable due to less muscular stabilization
  - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio

- Thessaly test
  - demonstrates meniscal tear
  - patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion
  - positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort
  - for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
  - for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio

- posterior sag sign
  - demonstrates torn PCL
  - may give a false positive anterior draw sign
  - flex knees and hips to 90°, hold ankles and knees
  - view from the lateral aspect
  - if one tibia sags posteriorly compared to the other, its PCL is torn

- pivot shift sign
  - demonstrates torn ACL
  - start with the knee in extension
  - internally rotate foot, slowly flex knee while palpating and applying a valgus force
  - normal knee will flex smoothly
  - if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the "pivot")
  - reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
  - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio

- collateral ligament stress test
  - palpate ligament for “opening” of joint space while testing
  - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  - repeat tests with knee in 20° flexion to relax joint capsule
  - opening in 20° flexion due to MCL damage only
  - opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage

- tests for meniscal tear
  - joint line tenderness
  - palpate one side at a time and watch patient’s eyes
  - for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
  - crouch compression test
  - joint line pain when squatting (anterior pain suggests patellofemoral pathology)
• McMurray’s test useful collaborative information
  • with knee in flexion, palpate joint line for painful “pop/click”
  • internally rotate foot, varus stress, and extend knee to test lateral meniscus
  • externally rotate foot, valgus stress, and extend knee to test medial meniscus
  • for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
• composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

X-Rays
• AP standing, lateral
• skyline: tangential view with knees flexed at 45° to see patellofemoral joint
• 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
• Ottawa Knee Rules (see Emergency Medicine, ER16)

Cruciate Ligament Tears

• ACL tear much more common than PCL tear

Table 21. Comparison of ACL and PCL Injuries

<td>Unstable knee or young person/high-demand lifestyle: ligament reconstruction</td>
</tr>
</tbody>
</table>

Collateral Ligament Tears

Mechanism
• valgus force to knee = MCL tear
• varus force to knee = LCL tear

Clinical Features
• swelling/effusion
• tenderness above and below joint line medially (MCL) or laterally (LCL)
• joint laxity with varus or valgus force to knee
  • laxity with endpoint suggests partial tear
  • laxity with no endpoint suggests a complete tear
• test for other injuries (e.g. O’Donoghue’s unhappy triad), common peroneal nerve injury

Investigations
• x-ray: AP and lateral; MRI

Treatment
• non-operative
  • partial tear: immobilization x 2-4 wk with early ROM and strengthening
  • complete tear: immobilization at 30° flexion
• operative
  • indication: multiple ligamentous injuries
  • surgical repair of ligaments

O’Donoghue’s Unhappy Triad
• ACL rupture
• MCL rupture
• Meniscal damage (medial and/or lateral)

Partial ligamentous tears are much more painful than complete ligamentous tears
Meniscal Tears

- medial tear much more common than lateral tear

Mechanism
- twisting force on knee when it is partially flexed (e.g. stepping down and turning)
- requires moderate trauma in young person but only mild trauma in elderly due to degeneration

Clinical Features
- immediate pain, difficulty weight-bearing, instability, and clicking
- increased pain with squatting and/or twisting
- effusion (hemarthrosis) with insidious onset (24-48 h after injury)
- joint line tenderness medially or laterally
- locking of knee (if portion of meniscus mechanically obstructing extension)

Investigations
- MRI, arthroscopy

Treatment
- non-operative
  - indication: not locked
  - ROM and strengthening (NSAIDs)
- operative
  - indication: locked or failed non-operative treatment
  - arthroscopic repair/partial meniscectomy

Quadriceps/Patellar Tendon Rupture

Mechanism
- sudden forceful contraction of quadriceps during an attempt to stop
- more common in obese patients and those with pre-existing degenerative changes in tendon
  - DM, SLE, RA, steroid use, renal failure on dialysis

Clinical Features
- inability to extend knee or weight-bear
- possible audible "pop"
- patella in lower or higher position with palpable gap above or below patella respectively
- may have an effusion

Investigations
- ask patient to straight leg raise (unable with complete rupture)
- knee x-ray to rule out patellar fracture, MRI to distinguish between complete and partial tears
- lateral view: patella alta with patella tendon rupture, patella baja (infra) with quadriceps tendon rupture

Treatment
- non-operative
  - indication: incomplete tears with preserved extension of knee
  - immobilization in brace
- operative
  - indication: complete ruptures with loss of extensor mechanism
  - early surgical repair: better outcomes compared with delayed repair (>6 wk post injury)
  - delayed repair complicated by quadriceps contracture, patella migration, and adhesions

Dislocated Knee

Mechanism
- high energy trauma
- by definition, caused by tears of multiple ligaments

Clinical Features
- classified by relation of tibia with respect to femur
  - anterior, posterior, lateral, medial, rotary
- knee instability
- effusion
- pain
- ischemic limb
- Schenck classification
Investigations
- x-ray: AP, lateral, skyline
- associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
- ankle brachial index (abnormal if <0.9)
- arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)

Treatment
- urgent closed reduction
- complicated by interposed soft tissue
- assessment of peroneal nerve, tibial artery, and ligamentous injuries
- emergent operative repair if vascular injury, open fracture or dislocation, non-reducible dislocation, compartment syndrome
- knee immobilization x 6-8 wk

Specific Complications
- high incidence of associated injuries
- popliteal artery tear
- peroneal nerve injury
- capsular tear
- chronic: instability, stiffness, post-traumatic arthritis

Patella

Patellar Fracture

Mechanism
- direct blow to the patella: fall, MVC (dashboard)
- indirect trauma by sudden flexion of knee against contracted quadriceps

Clinical Features
- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- ± effusion/hemarthrosis

Investigations
- x-rays: AP, lateral, skyline
- do not confuse with bipartite patella: congenitally unfused ossification centres with smooth margins on x-ray at superolateral corner

Treatment
- non-operative
  - indication: non-displaced (step-off <2-3 mm and fracture gap <1-4 mm)
    - straight leg immobilization 1-4 wk with hinged knee brace, weight bearing as tolerated
    - progress in flexion after 2-3 wk
    - physiotherapy: quadriceps strengthening when pain has subsided
- operative
  - indication: displaced (>2mm), comminuted, disrupted extensor mechanism
  - ORIF; if comminuted may require partial/complete patellectomy
  - goal: restore extensor mechanism with maximal articular congruency

Patellar Dislocation

Mechanism
- usually a non-contact twisting injury
- lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
- direct blow, e.g. knee/helmet to knee collision

Risk Factors
- young, female
- obesity
- high-riding patella (patella alta)
- knock-knees (genu valgus)
- Q-angle (quadriceps angle) ≥20°
- shallow intercondylar groove
- weak vastus medialis
- tight lateral retinaculum
- ligamentous laxity (Ehlers-Danlos)

Complications
- Symptomatic wiring
- Loss of reduction
- Osteonecrosis (proximal fragment)
- Hardware failure
- Knee stiffness
- Nonunion
- Infection

Figure 43. Types of patellar fractures

Figure 44. Q-angle
The angle between a vertical line through the patella and tibial tuberosity and a line from the ASIS to the middle patella; the larger the angle the greater the amount of lateral force on the knee (normal <20°)
**Clinical Features**
- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- positive patellar apprehension test
  - passive lateral translation results in guarding and patient apprehension
- often recurrent, self-reducing
- concomitant MCL injury
- increased Q-angle
- J-sign

**Investigations**
- x-rays: AP, lateral, skyline view of patella
  - check for fracture of medial patella (most common) and lateral femoral condyle

**Treatment**
- non-operative first
  - NSAIDs, activity modification, and physical therapy
  - short-term immobilization for comfort then 6 wk controlled motion
  - progressive weight bearing and isometric quadriceps strengthening
- operative
  - indication: if recurrent or if loose bodies present
  - surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

**Patellofemoral Syndrome (Chondromalacia Patellae)**
- syndrome of anterior knee pain associated with idiopathic articular changes of patella

**Risk Factors**
- malalignment causing patellar maltracking (Q angle ≥20°, genu valgus)
- post-treatment
- deformity of patella or femoral groove
- recurrent patellar dislocation, ligamentous laxity
- excessive knee strain (athletes)

**Mechanism**
- softening, erosion and fragmentation of articular cartilage, predominantly medial aspect of patella
- commonly seen in active young females

**Clinical Features**
- deep, aching anterior knee pain
  - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting or kneeling
- insidious onset and vague in nature
- sensation of instability, pseudolocking
- pain with extension against resistance through terminal 30-40°
- pain with compression of patella with knee ROM or resisted knee extension
- swelling rare, minimal if present
- palpable crepitus

**Investigations**
- x-ray: AP, lateral, skyline – may find chondrosis, lateral patellar tilt, patella alta/baja, or shallow sulcus
- CT-scan
- MRI – best to assess articular cartilage

**Treatment**
- non-operative
  - continue non-impact activities; rest and rehabilitation
  - NSAIDs
  - physiotherapy: vastus medialis and core strengthening
- operative
  - indication: failed non-operative treatment
  - tibial tubercle elevation
  - arthroscopic shaving/debridement
  - lateral release of retinaculum
Tibia

Tibial Plateau Fracture

Mechanism
• varus/valgus load ± axial loading (e.g. fall from height)
• femoral condyles driven into proximal tibia
• can result from minor trauma in osteoporotics

Clinical Features
• frequency: lateral > bicondylar > medial
• medial fractures require higher energy – often have concomitant vascular injuries
• knee effusion
• inability to bear weight
• swelling
• associated with compartment syndrome, ACL injury and meniscal tears
• Schatzker classification

Investigations
• x-ray: AP, lateral, oblique
• CT: pre-operative planning, identify articular depression and comminution
• ABI if any differences in pulses between extremities

Treatment

<table>
<thead>
<tr>
<th>Approach #1 (based on amount of depression seen on x-ray)</th>
<th>Non-operative indication (if depression on x-ray is &lt;3 mm): straight leg immobilization x 4-6 wk with progressive ROM weight bearing ORIF often requiring bone grafting to elevate depressed fragment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approach #2 (based on varus/valgus instability)</td>
<td>Non-operative indication (if minimal varus/valgus instability (&lt;15°)): straight leg immobilization x 4-6 wk with progressive ROM weight bearing Operative indication (if significant varus/valgus instability (&gt;15°)): ORIF often requiring bone grafting to elevate depressed fragment</td>
</tr>
</tbody>
</table>

Specific Complications (see General Fracture Complications, OR6)
• ligamentous injuries
• meniscal lesions
• AVN
• infection
• OA

Tibial Shaft Fracture

• most common long bone and open fracture

Mechanism
• low energy pattern: torsional injury
• high energy: including MVC, falls, sporting injuries

Clinical Features
• pain, inability to bear weight
• open vs. closed
• amount of displacement
• NVS

Investigations
• x-ray: AP, lateral, skyline
• full length, plus knee and ankle

Treatment

<table>
<thead>
<tr>

Low Molecular Weight Heparin for Prevention of Venous Thromboembolism in Patients with Lower-Leg Immobilization

Cochrane DB Syst Rev 2014;4:CD006681

Purpose: To evaluate the effectiveness of LMWH as VTE prophylaxis in patients with lower-leg immobilization in an ambulant setting.

Selection Criteria: RCTs and CCTs comparing LMWH to no prophylaxis or placebo in patients immobilized with a plaster cast or brace.

Results/Conclusions: 6 RCTs, 1,490 patients. Incidence of VTE was 4.3-40% in patients immobilized for >1wk without thromboprophylaxis or with placebo. With daily LMWH subcutaneous injections, incidence was 0-37% (OR 0.49, 95% CI 0.34-0.72). There were no reports of heparin-induced thrombocytopenia. The use of LMWH in outpatients with lower-leg immobilization significantly reduces the number of VTE events.
Ankle

Evaluation of Ankle and Foot Complaints

Special Tests
• anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
• talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by x-ray

X-Ray
• AP, lateral
• mortise view: ankle at 15° of internal rotation
  • gives true view of ankle joint
  • joint space should be symmetric with no talar tilt
• Ottawa Ankle Rules should guide x-ray use (see Emergency Medicine, ER17); nearly 100% sensitivity
• ± CT to better characterize fractures

Ankle Fracture

Mechanism
• pattern of fracture depends on the position of the ankle when trauma occurs
• generally involves
  • ipsilateral ligamentous tears or transverse bony avulsion
  • contralateral shear fractures (oblique or spiral)
• classification systems
  • Danis-Weber
  • Lauge-Hansen: based on foot’s position and motion relative to leg

Danis-Weber Classification
• based on level of fibular fracture relative to syndesmosis
• Type A (infra-syndesmotic)
  • pure inversion injury
  • avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
  • ± shear fracture of medial malleolus
• Type B (trans-syndesmotic)
  • external rotation and eversion (most common)
  • ± avulsion of medial malleolus or rupture of deltoid ligament
  • spiral fracture of lateral malleolus starting at plafond
• Type C (supra-syndesmotic)
  • pure external rotation
  • avulsion of medial malleolus or torn deltoid ligament
  • ± posterior malleolus avulsion with posterior tibio-fibular ligament
  • fibular fracture is above plafond (called Maisonneuve fracture if at proximal fibula)
  • frequently tears syndesmosis

Treatment
• non-operative
  • indication: non-displaced, no history of dislocation, usually lateral sided injury only
  • below knee cast, NWB
• operative
  • indications
    • any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
    • most of type B, and all of type C
    • trimalleolar (medial, posterior, lateral) fractures
    • talar tilt >10°
    • medial clear space on x-ray greater than superior clear space
    • open fracture/open joint injury
  • ORIF

Complications
• high incidence of post-traumatic arthritis
• wrinkle test: skin shows wrinkles, to determine if soft tissue swelling has resolved to an extent to reduce complications

Ottawa Ankle Rules (see Emergency Medicine, ER17)
X-rays are only required if:
Pain in the malleolar zone AND bony tenderness over the posterior aspect of the medial or lateral malleolus OR inability to weight bear both immediately after injury and in the ER

Figure 46. Ring principle of the ankle and Danis-Weber classification

Legend
1. Posterior malleolus
2. Medial malleolus
3. Deltoid ligament
4. Syndesmosis
5. Lateral malleolus
6. Calcaneofibular ligament
Ligamentous Injuries

• see Figure 48 for ankle ligaments

Medial Ligament Complex (deltoid ligament)
• eversion injury
• usually avulses medial or posterior malleolus and strains syndesmosis

Lateral Ligament Complex (Anterior Talofibular, Calcaneofibular, Posterior Talofibular)
• inversion injury, >90% of all ankle sprains
• ATF most commonly and severely injured if ankle is plantar flexed
• swelling and tenderness anterior to lateral malleolus
• ++ ecchymoses
• positive ankle anterior drawer
• may have significant medial talar tilt on inversion stress x-ray

Treatment
• non-operative
  ▪ microscopic tear (Grade I)
    ▪ rest, ice, compression, elevation (RICE)
  ▪ macroscopic tear (Grade II)
    ▪ strap ankle in dorsiflexion and eversion x 4-6 wk
    ▪ physiotherapy: strengthening and proprioceptive retraining
  ▪ complete tear (Grade III)
    ▪ below knee walking cast x 4-6 wk
    ▪ physiotherapy: strengthening and proprioceptive retraining
    ▪ surgical intervention may be required if chronic symptomatic instability develops

Foot

Talar Fracture

Mechanism
• axial loading or hyperdorsiflexion (MVC, fall from height)
• 60% of talus covered by articular cartilage
• talar neck is most common fracture of talus (50%)
• tenuous blood supply runs distal to proximal along talar neck
  ▪ high risk of AVN with displaced fractures

Investigations
• x-ray: AP, lateral, Canale view
• CT to better characterize fracture
• MRI can clearly define extent of AVN

Treatment
• non-operative
  ▪ indication: non-displaced
    ▪ NWB below knee cast x 6 weeks
  ▪ operative
    ▪ indication: displaced (Hawkin’s Classification)
      ▪ ORIF (high rate of nonunion, AVN)
    ▪ neck fracture: Pin (nondisplaced) or ORIF

Calcaneal Fracture

• most common tarsal fracture

Mechanism
• high energy, axial loading: fall from height onto heels
• 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
• 75% intra-articular and 10% are bilateral
Clinical Features
• marked swelling, bruising on heel/sole
• wider, shortened, flatter heel when viewed from behind
• varus heel

Investigations
• x-rays: AP, lateral, oblique (Broden’s view) Harris axial
• loss of Bohler’s angle
• CT: gold-standard, assess intra-articular extension

Treatment
• closed vs. open reduction is controversial
• NWB cast x 3 mo with early ROM and strengthening

Achilles Tendonitis
Mechanism
• chronic inflammation from activity or poor-fitting footwear
• may also develop heel bumps (retrocalcaneobursitis or Haglund deformity)

Clinical Features
• pain, stiffness, and crepitus with ROM
• thickened tendon, palpable bump

Investigations
• x-ray: lateral, evaluate bone spur and calcification; U/S, MRI (to assess degenerative change)

Treatment
• non-operative
  • rest, NSAIDs, shoe wear modification
  • heel sleeves and pads are mainstay of non-operative treatment
  • gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
  • orthotics, open back shoes
  • shockwave therapy in chronic tendinitis
  • DO NOT inject steroids (risk of tendon rupture)

Achilles Tendon Rupture
Mechanism
• loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
• secondary to chronic tendinitis, steroid injection

Clinical Features
• audible pop, sudden pain with push off movement
• sensation of being kicked in heel when trying to plantar flex
• palpable gap
• apprehensive toe off when walking
• weak plantar flexion strength
• Thompson test: with patient prone, plantar flexion when calf is squeezed by examiner
  • no passive plantar flexion is positive test = ruptured tendon

Investigations
• x-ray (to rule out other pathology), U/S or MRI (for partial vs complete ruptures)

Treatment
• non-operative
  • indication: low demand or elderly
  • cast foot in plantar flexion (to relax tendon) x 8-12 wk
• operative
  • indication: high demand
  • surgical repair, then cast as above x 6-8 wk

Complications of Achilles Tendon Rupture
• Infection
• Sural nerve injury
• Re-rupture: surgical repair decreases likelihood of re-rupture compared to non-operative management

Haglund Deformity: an enlargement of the posterior-superior tuberosity of the calcaneus

The most common site of Achilles tendon rupture is 2-6 cm from its insertion where the blood supply is the poorest
Plantar Fasciitis (Heel Spur Syndrome)

- Inflammation of plantar aponeurosis at calcaneal origin
- Common in athletes (especially runners, dancers)
- Also associated with obesity, DM, seronegative and seropositive arthritis

Mechanism
- Repetitive strain injury causing microtears and inflammation of plantar fascia
- Common in athletes (especially runners, dancers)
- Also associated with obesity, DM, seronegative and seropositive arthritis

Clinical Features
- Insidious onset of heel pain, pain when getting out of bed and stiffness
- Intense pain when walking from rest that subsides as patient continues to walk, worse at end of day with prolonged standing
- Swelling, tenderness over sole
- Greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
- Pain with toe dorsiflexion (stretches fascia)

Investigations
- Plain radiographs to rule out fractures
- Often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
- Spur is secondary to inflammation, not the cause of pain

Treatment
- Non-operative
  - Pain control and stretching programs are first line
  - Rest, ice, NSAIDs, steroid injection
  - Physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
  - Orthotics with heel cup – to counteract pronation and disperse heel strike forces
- Operative
  - Indication: failed non-operative treatment
  - Endoscopic surgical release of fascia
  - Spur removal is not required

Bunions (Hallux Valgus)

- Bony deformity characterized by medial displacement of first metatarsal and lateral deviation of hallux

Mechanism
- Valgus alignment on 1st MTP (hallux valgus) causes eccentric pull of extensor and intrinsic muscles
- Many associated deformities in foot from altered mechanics
- Reactive exostosis forms with thickening of the skin creating a bunion
- Most often associated with poor-fitting footwear (high heel and narrow toe box)
- Can be hereditary (70% have family history)
- 10x more frequent in women

Clinical Features
- Painful bursa over medial eminence of 1st MT head
- Pronation (rotation inward) of great toe
- Numbness over medial aspect of great toe

Investigations
- X-ray: standing AP/lateral/sesamoid view, NWB oblique

Treatment
- Indications: painful corn or bunion, overriding 2nd toe
- Non-operative (first line)
  - Properly fitted shoes (low heel) and toe spacer
- Operative: goal is to restore normal anatomy, not cosmetic reasons alone
  - Osteotomy with realignment of 1st MTP joint (Chevron Procedure)
  - Arthrodesis
Metatarsal Fracture

- as with the hand, 1st, 4th, 5th MT are relatively mobile, while the 2nd and 3rd are fixed
- use Ottawa Foot Rules to determine need for x-ray

Tarso-MT Fracture – Dislocation (Lisfranc Fracture) | Fall onto plantar flexed foot or direct crush injury | Shortened forefoot prominent base | ORIF |

*NWB BK = Non weight bearing, below knee

Pediatric Orthopedics

Fractures in Children

- type of fracture
  - thicker, more active periosteum results in pediatric specific fractures: greenstick (one cortex), torus (i.e. ‘buckle’, impacted cortex) and plastic (bowing)
  - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
  - adults fracture through both cortices
- epiphyseal growth plate
  - weaker part of bone, susceptible to fractures
  - plate often mistaken for fracture on x-ray and vice versa (x-ray opposite limb for comparison), especially in elbow
  - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
  - intra-articular fractures have worse consequences in children because they usually involve the growth plate
- anatomic reduction
  - gold standard with adults
  - may cause limb length discrepancy in children (overgrowth)
  - accept greater angular deformity in children (remodelling minimizes deformity)
- time to heal
  - shorter in children
- always be aware of the possibility of child abuse
  - make sure stated mechanism compatible with injury
  - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including x-ray evidence of healing fractures at different sites and different stages of healing

Stress Fractures

Mechanism
- insufficiency fracture
  - stress applied to a weak or structurally deficient bone
- fatigue fracture
  - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- tibia is most common site

Diagnosis
- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan positive in 12-15 d

Treatment
- rest from strenuous activities to allow remodelling (can take several months)
Evaluation of the Limping Child

• see Pediatrics, P91

Epiphyseal Injury

Table 23. Salter-Harris Classification of Epiphyseal Injury

<table>

<tr>
<td>III (Low)*</td>
<td>Through epiphysis to plate and along growth plate</td>
<td>Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate</td>
</tr>
<tr>
<td>IV (Through and through)*</td>
<td>Through epiphysis and metaphysis</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>V (Ram)*</td>
<td>Crush injury of growth plate</td>
<td>High incidence of growth arrest; no specific treatment</td>
</tr>
</tbody>
</table>

* Types III – IV are more likely to cause growth arrest and progressive deformity

Slipped Capital Femoral Epiphysis

• type I Salter-Harris epiphyseal injury at proximal hip
• most common adolescent hip disorder, peak incidence at pubertal growth spurt
• risk factors: male, obese (#1 factor), hypothyroid (risk of bilateral involvement)

Etiology

• multifactorial
  ▪ genetic: autosomal dominant, blacks > caucasians
  ▪ cartilaginous physis hypertrophies too rapidly under growth hormone effects
  ▪ sex hormone secretion, which stabilizes physis, has not yet begun
  ▪ overweight: mechanical stress
  ▪ trauma: causes acute slip

Clinical Features

• acute: sudden, severe pain with limp
• chronic (typically): groin and anterior thigh pain, may present with knee pain
  ▪ positive Trendelenburg sign on affected side, due to weakened gluteal muscles
• tender over joint capsule
• restricted internal rotation, abduction, flexion
  ▪ Whitman’s sign: obligatory external rotation during passive flexion of hip
• Loder classification: stable vs. unstable (provides prognostic information)
  ▪ unstable means patient cannot ambulate even with crutches

Investigations

• x-ray: AP, frog-leg, lateral radiographs both hips
  ▪ posterior and medial slip of epiphysis
  ▪ disruption of Klein’s line
  ▪ AP view may be normal or show widened/lucent growth plate compared with opposite side

Treatment

• operative
  ▪ mild/moderate slip: stabilize physis with pins in current position
  ▪ severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion

Complications

• AVN (roughly half of unstable hips), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM
Developmental Dysplasia of the Hip

- abnormal development of hip resulting in dysplasia and subluxation/dislocation of hip
- most common orthopedic disorder in newborns

Etiology
- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions that lead to hip subluxation and dislocation
  - dislocated femoral head completely out of acetabulum
  - dislocatable head in socket
  - head subluxates out of joint when provoked
  - dysplastic acetabulum, more shallow and more vertical than normal
- painless (if painful suspect septic dislocation)

Physical Exam
- diagnosis is clinical
  - limited abduction of the flexed hip (<50-60°)
  - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  - Barlow’s test (for dislocatable hip)
    - flex hips and knees to 90° and grasp thigh
    - fully adduct hips, push posteriorly to try to dislocate hips
  - Ortolani’s test (for dislocated hip)
    - initial position as above but try to reduce hip with fingertips during abduction
    - positive test: palpable clunk is felt (not heard) if hip is reduced
  - Galeazzi’s sign
    - knees at unequal heights when hips and knees flexed
    - dislocated hip on side of lower knee
  - difficult test if child <1 yr
  - Trendelenburg test and gait useful if older (>2 yr)

Investigations
- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow up radiograph after 3 mo
- x-ray signs (at 4-6 mo): false acetabulum, acetabular index >25°, broken Shenton’s line, femoral neck above Hilgenreiner’s line, ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner’s and Perkin’s line)

Treatment
- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- >18 mo: open reduction; pelvic and/or femoral osteotomy

Complications
- redislocation, inadequate reduction, stiffness
- AVN of femoral head

Legg-Calvé-Perthes Disease (Coxa Plana)

- idiopathic AVN of femoral head, presents at 4-8 yr of age
- 12% bilateral, M>F = 5:1, 1/1,200
- associations
  - family history
  - low birth weight
  - abnormal pregnancy/delivery
  - ADHD in 33% of cases, delayed bone age in 89%
  - second-hand smoke exposure
  - Asian, Inuit, Central European
- key features
  - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Clinical Features
- child with antalgic or Trendelenburg gait ± pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip): decreased internal rotation and abduction of hip
- limb length discrepancy (late)
Investigations
• x-ray: AP pelvis, frog leg laterals
  ▪ may be negative early (if high index of suspicion, move to bone scan or MRI)
  ▪ eventually, characteristic collapse of femoral head (diagnostic)

Treatment
• goal is to preserve ROM and keep femoral head contained in acetabulum
• non-operative
  ▪ physiotherapy: ROM exercises
  ▪ brace in flexion and abduction x 2-3 yr (controversial)
• non-operative
  ▪ femoral or pelvic osteotomy (>8 yr of age or severe)
    ▪ prognosis better in males, <5 yr, <50% of femoral head involved, abduction >30°
  ▪ 60% of involved hips do not require operative intervention
  ▪ natural history is early onset OA and decreased ROM

Osgood-Schlatter Disease
• inflammation of patellar ligament at insertion point on tibial tuberosity
• M>F
• age of onset: boys 12-15 yr; girls 8-12 yr

Mechanism
• repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor
  avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features
• tender lump over tibial tuberosity
• pain on resisted leg extension
• anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations
• x-ray: lateral knee: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

Treatment
• benign, self-limited condition, does not resolve until growth halts
• majority non-operative
  ▪ may restrict activities such as basketball or cycling
  ▪ NSAIDs, rest, flexibility, isometric strengthening exercises
  ▪ casting if symptoms do not resolve with conservative management
• operative: ossicle excision in refractory cases (patient is skeletally mature with persistent
  symptoms)

Congenital Talipes Equinovarus (Club Foot)
• congenital foot deformity
• muscle contractures resulting in CAVE deformity
• bony deformity: talar neck medial and plantar deviated; varus calcaneus and rotated medially
  around talus; navicular and cuboid medially displaced
• 1-2/1,000 newborns, 50% bilateral, occurrence M>F, severity F>M

Etiology
• intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine
  growth restriction), may be idiopathic, neurogenic, or syndrome-associated
• fixed deformity

Physical Exam
• examine hips for associated DDH
• examine knees for deformity
• examine back for dysraphism (unfused vertebral bodies)

Treatment
• largely non-operative via Ponseti Technique (serial manipulation and casting)
  ▪ correct deformities in CAVE order
    ▪ change strapping/cast q1-2wk
    ▪ surgical release in refractory case (rare)
      ▪ delayed until 3-4 mo of age
• 3 yr recurrence rate = 5-10%
• mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf
  muscle atrophy
**Scoliosis**

- lateral curvature of spine with vertebral rotation
- age: 10-14 yr
- more frequent and more severe in females

**Etiology**
- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

**Clinical Features**
- ± back pain
- primary curve where several vertebrae affected
- secondary curves above and below fixed 1st curve to try and maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam's test: rib hump when bent forward
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scolioses
  - café-au-lait spots, dimples, neurofibromas
  - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

**Investigations**
- x-ray: 3-foot standing, AP, lateral
  - measure curvature: Cobb angle
  - may have associated kyphosis

**Treatment**
- based on Cobb angle
  - <25°: observe for changes with serial radiographs
  - >25° or progressive: bracing (many types) that halt/slow curve progression but do NOT reverse deformity
  - >45°, cosmetically unacceptable or respiratory problems: surgical correction (spinal fusion)

**Bone Tumours**

- primary bone tumours are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

**Clinical Features**
- malignant (primary or metastasis): local pain and swelling (wk – mo), worse on exertion and at night, ± soft tissue mass
- benign: usually asymptomatic
- minor trauma often initiating event that calls attention to lesion

**Table 24. Distinguishing Benign from Malignant Bone Lesions on X-Ray**

</tbody>
</table>

**Diagnosis**
- routine x-ray findings
  - location (which bone, diaphysis, metaphysis, epiphysis)
  - size
  - lytic/lucent vs. sclerotic
  - involvement (cortex, medulla, soft tissue)
• matrix (radiolucent, radiodense or calcified)
• periosteal reaction
• margin (geographic vs. permeative)
• any pathological fracture
• soft tissue swelling
• malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
• staging should include
  • blood work including liver enzymes
  • CT chest
  • bone scan
  • bone biopsy
    • should be referred to specialized centre prior to biopsy
    • classified into benign, benign aggressive, and malignant
  • MRI of affected bone

Benign Active Bone Tumours

BONE-FORMING TUMOURS

Osteoid Osteoma
• bone tumour arising from osteoblasts
• peak incidence in 2nd and 3rd decades, M:F = 2:1 (young males)
• proximal femur and tibia diaphysis most common locations
• not known to metastasize
• radiographic findings: small, round radiolucent nidus (<1.5 cm) surrounded by dense sclerotic bone (“bull’s-eye”)
• symptoms: produces severe intermittent pain from prostaglandin secretion and COX1/2 expression, mostly at night (diurnal prostaglandin production), thus is characteristically relieved by NSAIDs
• treatment: NSAIDs for night pain; surgical resection of nidus

FIBROUS LESIONS

Fibrous Cortical Defect
• or non-ossifying fibroma; fibrous bone lesion
• most common benign bone tumour in children, typically asymptomatic and an incidental finding
• occur in as many as 35% of children, peak incidence between 2-25 yr old, higher prevalence in males
• femur and proximal tibia most common locations, 50% of patients have multiple defects usually bilateral, symmetrical
• radiographic findings: diagnostic, metaphyseal eccentric ‘bubbly’ lytic lesion near physis; thin smooth/lobulated well-defined sclerotic margin
• treatment: most lesions resolve spontaneously

Osteochondroma
• cartilage capped bony tumour
• 2nd and 3rd decades, M:F = 1.8:1
• most common of all benign bone tumours – 45%
• 2 types: sessile (broad based and increased risk of malignant degeneration) vs. pedunculated (narrow stalk)
• metaphysis of long bone near tendon attachment sites (usually distal femur, proximal tibia, or proximal humerus)
  • radiographic findings: cartilage-capped bony spur on surface of bone (“mushroom” on x-ray)
  • may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
• generally very slow growing and asymptomatic unless impinging on neurovascular structure (‘painless mass’)
• growth usually ceases when skeletal maturity is reached
• malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)
• treatment: typically observation; surgical excision if symptomatic

Enchondroma
• hyaline cartilage tumour; majority asymptomatic, presenting as incidental finding or pathological fracture
• 2nd and 3rd decades
• 60% occur in the small tubular bones of the hand and foot; others in femur (20%), humerus, ribs

Figure 57. T1 MRI of femoral enchondroma
• benign cartilagenous growth, an abnormality of chondroblasts, develops in medullary cavity
  ▪ single/multiple enlarged rarefied areas in tubular bones
  ▪ lytic lesion with sharp margination and irregular central calcification (stippled/punctate/popcorn appearance)
• malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
• not known to metastasize
• treatment: observation with serial x-rays; surgical curettage if symptomatic or lesion grows

CYSTIC LESIONS

Unicameral/Solitary Bone Cyst
• most common cystic lesion; serous fluid filled lesion
• children and young adults, peak incidence during first 2 decades, M:F = 2:1
• proximal humerus and femur most common
• symptoms: asymptomatic, or local pain; complete pathological fracture (50% presentations) or incidental detection
• radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well defined lesion
• treatment: aspiration followed by steroid injection; curettage ± bone graft indicated if re-fracture likely

Benign Aggressive Bone Tumours

Giant Cell Tumours/Aneurysmal Bone Cyst/Osteoblastoma
• affects patients of skeletal maturity, peak 3rd decade
• osteoblastoma: found in the distal femur, proximal tibia, distal radius, sacrum, tarsal bones, spine
• giant cell tumour: pulmonary metastases in 3%
• aneurysmal bone cysts: either solid with fibrous/granular tissue, or blood-filled
• radiographic findings
  ▪ giant cell tumour: eccentric lytic lesions, in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
  ▪ aneurysmal bone cyst: expanded with honeycomb shape
  ▪ osteoblastoma: often nonspecific; calcified central nidus (>2 cm) with radiolucent halo and sclerosis
• symptoms: local tenderness and swelling, pain may be progressive (giant cell tumours), ± symptoms of nerve root compression (osteoblastoma)
• 15% recur within 2 yr of surgery

Treatment
• intralesional curettage + bone graft or cement
• wide local excision of expendable bones

Malignant Bone Tumours

<table>

</tr>
</tbody>
</table>

Osteosarcoma
• malignant bone tumour
• most frequently diagnosed in 2nd decade of life (60%), 2nd most common primary malignancy in adults
• history of Paget’s disease (elderly patients), previous radiation treatment
• predilection for sites of rapid growth: distal femur (45%), proximal tibia (20%), and proximal humerus (15%)
  ▪ invasive, variable histology; frequent metastases without treatment (lung most common)
• painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
• radiographic findings
  ▪ characteristic periosteal reaction: Codman’s triangle (see Figure 56) or “sunburst” spicule formation (tumour extension into periosteum)
  ▪ destructive lesion in metaphysis may cross epiphyseal plate
• management: complete resection (limb salvage, rarely amputation), neo-adjuvant chemo; bone scan – rule out skeletal metastases, CT chest – rule out pulmonary metastases
• prognosis: 70% (high-grade); 90% (low-grade)

Chondrosarcoma
• malignant chondrogenic tumour
• primary (2/3 cases)
  • previous normal bone, patient >40 yr; expands into cortex to give pain, pathological fracture, flecks of calcification
• secondary (1/3 cases)
  • malignant degeneration of pre-existing cartilage tumour such as enchondroma or osteochondroma
  • age range 25-45 yr and better prognosis than primary chondrosarcoma
• symptoms: progressive pain, uncommonly palpable mass
• radiographic findings: in medullary cavity, irregular “popcorn” calcification
• treatment: unresponsive to chemotherapy, treat with aggressive surgical resection + reconstruction; regular follow-up x-rays of resection site and chest
• prognosis: 10-yr survival 90% low-grade, 20-40% high-grade

Ewing’s Sarcoma
• malignant small round cell sarcoma
• most occur between 5-25 yr old
• florid periosteal reaction in metaphyses of long bone with diaphysal extension
• metastases frequent without treatment
• signs/symptoms: presents with pain, mild fever, erythema and swelling, anemia, increased WBC, ESR, LDH (mimics an infection)
• radiographic findings: moth-eaten appearance with periosteal lamellated pattern (“onion-skinning”)
• treatment: resection, chemotherapy, radiation
• prognosis – 70%, worst prognostic factor is distant metastases

Multiple Myeloma
• proliferation of neoplastic plasma cells
• most common primary malignant tumour of bone in adults (~43%)
• 90% occur in people >40 yr old, M:F = 2:1, African-Americans (twice as common)
• signs/symptoms: localized bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
• labs: anemia, thrombocytopenia, increased ESR, hypercalcemia, increased Cr
• radiographic findings: multiple, “punched-out” well-demarcated lesions, no surrounding sclerosis, marked bone expansion
• diagnosis
  • serum/urine immunoelectrophoresis (monoclonal gammopathy)
  • CT-guided biopsy of lytic lesions at multiple bony sites
• treatment: chemotherapy, bisphosphonates, radiation, surgery for symptomatic lesions or impending fractures – debulking, internal fixation
• prognosis: 5 yr survival 30%; 10 yr survival 11%
• see Hematology, H49

Bone Metastases
• most common cause of bone lesions in adults; typically age >40
• 2/3 from breast or prostate; also consider thyroid, lung, kidney
• usually osteolytic; prostate occasionally osteoblastic
• may present with mechanical pain and/or night pain, pathological fracture, hypercalcemia
• bone scan for MSK involvement, MRI for spinal involvement may be helpful
• treatment: pain control, bisphosphonates, stabilization of impending fractures if Mirel’s Criteria >8 (ORIF, IM rod, bone cement)

</table>
| LMWH | dalteparin (Fragmin®)  
enoxaparin (Lovenox®)  
fondaparinux (Arixtra®) | 5000 IU SC OD  
30-40 mg SC bid  
2.5 mg SC OD | DVT prophylaxis especially in hip and knee surgery | Fixed dose, no monitoring, improved bioavailability, increased bleeding rates |
| oral anticoagulants | dabigatran (Pradaxa®)  
rivaroxaban (Xarelto®)  
apixaban | 110 mg PO x1 then 220 mg PO OD  
10 mg PO OD  
2.5 mg PO bid | DVT prophylaxis especially TKA and THA | Predictable, no monitoring, oral administration; no antidote |
| midazolam (Versed®) | 0.02-0.04 mg/kg IV | Conscious sedation for short procedures | Medication used during fracture reduction – monitor for respiratory depression |
| fentanyl (Sublimaze®) | 0.5-3 µg/kg IV | Conscious sedation for short procedures | Short acting anesthetic used in conjunction with midazolam (Versed®) |
| triamcinolone (Aristocort®) – an injectable steroid | 0.5-1 mL of 25 mg/mL suspension | Suspension (injected into inflamed joint or bursa); amount varies by joint size | Potent anti-inflammatory effect; increased pain for 24 h; rarely causes fat necrosis and skin depigmentation |
| naproxen (Aleve®, Naprosyn®) | 250-500 mg bid | Pain due to inflammation, arthritis, soft tissue injury | NSAID, may cause gastric erosion and bleeding |
| misoprostol (Cytotec®) | 200 µg qid | Prophylaxis of HO after THA | Use with indomethacin |
| indomethacin (Indocid®) | 25 mg PO tid | Prophylaxis of HO after THA | Use with misoprostol |
| ibuprofen (Advil®, Motrin®) | 200-400 mg tid | Pain (including post-operative), inflammation (including arthritis) | NSAID, may cause gastric erosion and bleeding |
| propofol (Diprivan®) | 1-2 mg/kg IV maintenance 0.5 mg/kg | Conscious sedation for short procedures | Short acting anesthetic often used in conjunction with fentanyl (Sublimaze®) |

Anatomical Triangles of the Neck

Anterior triangle
- bounded by anterior border of SCM, midline of neck, and lower border of mandible
- divided into
  - submental triangle: bounded by both anterior bellies of digastric and hyoid bone
  - digastric triangle: bounded by anterior and posterior bellies of digastric and inferior border of mandible
  - carotid triangle: bounded by sternocleidomastoid, anterior belly of omohyoid, and posterior belly of digastric
    - contains: tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

Posterior triangle
- bounded by posterior border of sternocleidomastoid, anterior border of trapezius, and middle third of clavicle
- divided into
  - occipital triangle: superior to posterior belly of the omohyoid
  - subclavian triangle: inferior to posterior belly of omohyoid
- contains: spinal accessory nerve and lymph nodes

Differential Diagnoses of Common Presenting Problems

**Dizziness**

- **Peripheral (Vestibular)**
  - Benign paroxysmal positional vertigo (BPPV)
  - Labyrinthitis
  - Meniere's disease
  - Vestibular neuritis
  - Autoimmune inner ear disease
  - Cholesteatoma
  - Ototoxic drug exposure
  - Perilymph fistula
  - Recurrent vestibulopathy
  - Superior semicircular canal dehiscence
  - Temporal bone fracture

- **Central**
  - Cerebrovascular disorders
    - Vertebrobasilar insufficiency
    - Transient ischemic attacks
    - Wallenberg's syndrome
    - Cerebellar infarction
    - Migraine vertigo
    - Multiple sclerosis
    - Inflammation
    - Meningitis
    - Cerebellar abscess
    - Trauma: cerebellar contusion
    - Toxic: alcohol, hypnotics, drugs
    - Tumours
    - CPA tumours
    - Posterior fossa tumours
    - Glomus tumours

- **Organic Diseases**
  - Cardiac
    - Arrhythmias
    - Aortic stenosis
    - Vasovagal
    - Orthostatic hypotension
    - Anemia
    - Periperal neuropathy
    - Visual impairment

- **Non-Vertiginous**
  - Depression
  - Anxiety
  - Panic disorder
  - Hyperventilation
  - Personality disorder
  - Phobic dizziness

**Common causes in bold**

True nystagmus and vertigo caused by a peripheral lesion will never last longer than a couple of weeks because of compensation. Central lesions do not compensate, hence nystagmus and vertigo will persist.

Lung malignancy is the most common cause of extralaryngeal vocal cord paralysis
Neck Mass

Inflammatory/Infections
- Reactive lymphadenopathy
- TB or atypical mycobacteria
- Infectious mononucleosis
- Abscesses
- Cat scratch fever
- Sarcoidosis
- Kawasaki disease
- HIV

Congenital
- Thyroglossal duct cyst
- Thyroid tumour/goitre
- Pyramidal lobe of thyroid gland
- Ranula

Neoplasic
- Branchial cleft cyst
- Cystic hygroma
- Lymphoma
- Thyroid
- Sarcoma
- Salivary gland neoplasm
- Rhabdomyosarcoma
- Neuroblastoma

Malignant
- Head and neck primary
- Infraclavicular primary
- Leukemia

Benign
- Salivary gland neoplasm
- Lipoma
- Fibroma
- Vascular

Hearing

Normal Hearing Physiology

- **Conductive pathway (external auditory canal to cochlea):** air conduction of sound energy down the EAC → vibration of the tympanic membrane (area effect) → sequential vibration of the middle ear ossicles: malleus, incus, stapes (lever effect) → transmission of amplified vibrations from the stapes footplate in the middle ear to the oval window of the cochlea in the inner ear → pressure differential on cochlear fluid creates movement along the basilar membrane within the cochlea from base to apex
- **Neural pathway (nerve to brain):** basilar membrane vibration stimulates overlying hair cells in the organ of Corti → stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII → cochlear nucleus → superior olivary nucleus → lateral lemniscus → inferior colliculus → Sylvian fissure of temporal lobe

Types of Hearing Loss

1. **Conductive Hearing Loss**
   - conduction of sound to the cochlea is impaired
   - can be caused by external and middle ear disease

2. **Sensorineural Hearing Loss**
   - due to a defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
   - can be caused by disease of the inner ear (cochlea), acoustic nerve (CN VIII), brainstem, or cortex

3. **Mixed Hearing Loss**
   - combination of conductive and sensorineural hearing loss

**Auditory Acuity**
- whispered-voice test: mask one ear and whisper into the other
- tuning fork tests (see Table 4; audiogram is of greater utility)
- sensitivity depends on which tuning fork used (256 Hz, 512 Hz, 1024 Hz; 512 Hz has the greatest sensitivity)
  - **Rinne test**
    - 512 Hz tuning fork is struck and held firmly on mastoid process to test BC; the tuning fork is then placed beside the pinna to test AC
    - If AC > BC → positive Rinne (normal)
  - **Weber test**
    - 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
    - can place vibrating fork on patient’s chin while they clench their teeth, or directly on teeth to elicit more reliable response
    - will only lateralize if difference in hearing loss between ears is >6 dB
### Pure Tone Audiometry

- A threshold is the lowest intensity level at which a patient can hear the tone 50% of the time.
- Thresholds are obtained for each ear at frequencies of 250, 500, 1000, 2000, 4000, and 8000 Hz.
- Air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function.
- Bone conduction thresholds are obtained with bone conduction oscillators which bypass the outer and middle ear.

### Degree of Hearing Loss

- Determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz.

### Table 4. The Interpretation of Tuning Fork Tests

<table>
<thead>
<tr>
<th>Examples</th>
<th>Weber</th>
<th>Rinne</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal or bilateral sensorineural hearing loss</td>
<td>Central</td>
<td>AC &gt; BC (+) bilaterally</td>
</tr>
<tr>
<td>Right-sided conductive hearing loss, normal left ear</td>
<td>Lateralizes to right</td>
<td>BC &gt; AC (–) right</td>
</tr>
<tr>
<td>Right-sided sensorineural hearing loss, normal left ear</td>
<td>Lateralizes to left</td>
<td>AC &gt; BC (+) bilaterally</td>
</tr>
<tr>
<td>Right-sided severe sensorineural hearing loss or dead right ear, normal left ear</td>
<td>Lateralizes to left</td>
<td>BC &gt; AC (–) right*</td>
</tr>
</tbody>
</table>

*A vibrating tuning fork on the mastoid stimulates the cochlea bilaterally, therefore in this case the left cochlea is stimulated by the Rinne test on the right (e.g. a false negative test). These tests are not valid if the ear canals are obstructed with cerumen (e.g. will create conductive loss).

### Frequency of Tuning Fork

<table>
<thead>
<tr>
<th>Frequency (Hz)</th>
<th>Minimum Hearing Loss for Rinne to Reverse (BC &gt; AC, NEGATIVE Rinne) (dB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>256</td>
<td>15</td>
</tr>
<tr>
<td>512</td>
<td>30</td>
</tr>
<tr>
<td>1024</td>
<td>45</td>
</tr>
</tbody>
</table>

### Range of Frequencies Audible to Human Ear

- 20 to 20000 Hz
- Most sensitive frequencies: 1000 to 4000 Hz
- Range of human speech: 500 to 2000 Hz

### Hearing loss most often occurs at higher frequencies. Noise-induced (occupational) HL is classically seen at 4000 Hz. HL associated with otosclerosis is seen at 2000 Hz (Carhart’s notch).

### PURE TONE PATTERNS

1. **Conductive Hearing Loss** (Figure 16B and 16C)
   - BC in normal range
   - AC outside of normal range
   - Gap between AC and BC thresholds > 10 dB (an air-bone gap)

2. **Sensorineural Hearing Loss** (Figure 16D and 16E)
   - Both air and bone conduction thresholds below normal
   - Gap between AC and BC < 10 dB (no air-bone gap)

3. **Mixed Hearing Loss**
   - Both air and bone conduction thresholds below normal
   - Gap between AC and BC thresholds > 10 dB (an air-bone gap)
Speech Audiometry

Speech Reception Threshold
- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- SRT and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB; if not, suspect a retrocochlear lesion or functional hearing loss
- used to assess the reliability of the pure tone audiometry

Speech Discrimination Test
- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at 40 dB above the patient’s SRT, therefore degree of hearing loss is taken into account
- patients with normal hearing or conductive hearing loss score >90%
- score depends on extent of SNHL
- rollover effect: a decrease in discrimination as sound intensity increases; typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears as asymmetry may indicate a retrocochlear lesion
- used as best predictor of hearing aid response: a poor discrimination score indicates significant neural degeneration and hearing aids may not be the best option for the patient

Impedance Audiometry

Tympnogram
- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from to –400 to +200 mmH₂O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: –100 to +50 mmH₂O

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>High compliance</td>
</tr>
<tr>
<td></td>
<td>Normal pressure peak at 0</td>
</tr>
<tr>
<td></td>
<td>Note: with otosclerosis, peak is still at 0 mmH₂O but has a lower amplitude</td>
</tr>
<tr>
<td></td>
<td>Note: with ossicular chain discontinuity, peak is still at 0 mmH₂O but has a higher amplitude</td>
</tr>
<tr>
<td>B</td>
<td>No pressure peak</td>
</tr>
<tr>
<td></td>
<td>Poor TM mobility indicative of middle ear effusion (OME) or perforated TM</td>
</tr>
<tr>
<td>C</td>
<td>Negative pressure peak</td>
</tr>
<tr>
<td></td>
<td>Indicative of Eustachian tube dysfunction or early stage otitis media without effusion</td>
</tr>
</tbody>
</table>

Figure 17. Tympnograms

Static Compliance
- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0.3-1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of >2 cc in children and 2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

Acoustic Stapedial Reflexes
- stapedius muscle contracts in response to loud sound
- **acoustic reflex threshold** = 70-100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
- stimulating either ear causes bilateral and symmetrical reflexes
- for reflex to be present, CN VII must be intact and no conductive hearing loss in monitored ear
- if reflex is absent without conductive or severe sensorineural loss, suspect CN VII lesion
- **acoustic reflex decay test** = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
- normally, little reflex decay occurs at 500 and 1000 Hz
- with cochlear hearing loss, acoustic reflex thresholds are 25-60 dB
- with retrocochlear hearing loss (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s
Auditory Brainstem Response

- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (see Order of Neural Pathway sidebar on OT9); this test can be used to determine the site of lesion
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore of value in children and in malingers)

Otoacoustic Emissions

- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- often used in newborn screening
- can be used to uncover normal hearing in malingers
- absence of emissions can be due to hearing loss or fluid in the middle ear

Aural Rehabilitation

- dependent on degree of hearing loss, communicative requirements, motivation, expectations, and physical and mental abilities
- negative prognostic factors
  - poor speech discrimination
  - narrow dynamic range (recruitment)
  - unrealistic expectations
- types of hearing aids
  - BTE: behind-the-ear (with occlusive mould or open fit which allows natural sound to pass – for milder hearing losses)
  - ITE: in-the-ear, placed in concha
  - ITC: in-the-canal, placed entirely in ear canal
  - CIC: contained-in-canal, placed deeply in ear canal
  - bone conduction – bone-anchored hearing aid (BAHA): attached to the skull
  - contralateral routing of signals (CROS)
- assistive listening devices
  - direct/indirect audio output
  - infrared, FM radio, or induction loop systems
  - telephone, television, or alerting devices
- cochlear implants
  - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
  - for profound bilateral sensorineural hearing loss not rehabilitated with conventional hearing aids
  - established indication: post-lingually deafened adults, pre- and post-lingually deaf children

Vertigo

Evaluation of the Dizzy Patient

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
  - vertigo is produced by peripheral (inner ear) or central (brainstem-cerebellum) stimulation
  - it is important to distinguish vertigo from other disease entities that may present with similar complaints of “dizziness” (e.g. cardiovascular, psychiatric, neurological, aging)

</table>

Benign Paroxysmal Positional Vertigo

Definition
- acute attacks of transient rotatory vertigo lasting seconds to minutes initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)
- most common form of positional vertigo (50% of patients with peripheral vestibular dysfunction)

Etiology
- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
  - can affect each of the 3 semicircular canals, although the posterior canal is affected in >90% of cases
  - causes: head injury, viral infection (URTI), degenerative disease, idiopathic
  - results in slightly different signals being received by the brain from the two balance organs resulting in sensation of movement

Diagnosis
- history (time course, provoking factors, associative symptoms)
- positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

Dix-Hallpike Positional Testing (see website for video and illustrations)
- the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45° and neck extended 20° holding the position for 20 s
- onset of vertigo and rotary nystagmus indicate a positive test for the dependent side
- other diagnostic testing is not indicated in posterior canal BPPV

Treatment
- reassure patient that process resolves spontaneously
- particle repositioning maneuvers
  - Epley maneuver (performed by MD)
  - Brandt-Daroff exercises (performed by patient)
- surgery for refractory cases
- anti-emetics for N/V
- drugs to suppress the vestibular system delay eventual recovery and are therefore not used

Menière’s Disease (Endolymphatic Hydrops)

Definition
- episodic attacks of tinnitus, hearing loss, aural fullness, and vertigo lasting minutes to hours

Proposed Etiology
- inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth
Epidemiology
- peak incidence 40-60 yr
- bilateral in 35% of cases

Clinical Features
- episodic vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness
- ± drop attacks (Tumarkin crisis), ± N/V
- vertigo disappears with time (min to h), but hearing loss remains
- early in the disease: fluctuating SNHL
- later stages: persistent tinnitus and progressive hearing loss
- attacks come in clusters and can be debilitating to the patient
- triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment
- acute management may consist of bed rest, antiemetics, antivertiginous drugs (e.g. betahistine [Serc®]), and low molecular weight dextrans (not commonly used)
- long-term management may include
  - medical
    - low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
    - Serc® prophylactically to decrease intensity of attacks
    - local application of gentamicin to destroy vestibular end-organ, results in complete SNHL
  - surgical
    - selective vestibular neurectomy or transtympanic labyrinthectomy
    - vestibular implants have recently been introduced experimentally
- must monitor opposite ear as bilaterality occurs in 35% of cases

Vestibular Neuronitis

Definition
- acute onset of disabling vertigo often accompanied by N/V and imbalance without hearing loss that resolves over days leaving a residual imbalance that lasts days to weeks

Etiology
- thought to be due to a viral infection (e.g. measles, mumps, herpes zoster)
- ~30% of cases have associated URTI symptoms
- other: microvascular events, diabetes, autoimmune process
- considered to be the vestibular equivalent of Bell's palsy, sudden hearing loss, and acute vocal cord palsy

Clinical Features
- acute phase
  - severe vertigo with N/V and imbalance lasting 1-5 d
  - irritative nystagmus (fast phase towards the offending ear)
  - patient tends to veer towards affected side
- convalescent phase
  - imbalance and motion sickness lasting days to weeks
  - spontaneous nystagmus away from affected side
  - gradual vestibular adaptation requires weeks to months
- incomplete recovery likely with the following risk factors: elderly, visual impairment, poor ambulation
- repeated attacks can occur

Treatment
- acute phase
  - bed rest, vestibular sedatives (Gravol®), diazepam
- convalescent phase
  - progressive ambulation especially in the elderly
  - vestibular exercises: involve eye and head movements, sitting, standing, and walking

Labyrinthitis

Definition
- acute infection of the inner ear resulting in vertigo and hearing loss

Etiology
- may be serous (viral) or purulent (bacterial)
- occurs as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures
- bacterial: S. pneumoniae, H. influenzae, M. catarrhalis, P. aeruginosa, P. mirabilis
- viral: rubella, CMV, measles, mumps, varicella zoster
Clinical Features
• sudden onset of vertigo, N/V, tinnitus, and unilateral hearing loss with no associated fever or pain
• meningitis is a serious complication

Investigations
• CT head
• if meningitis is suspected: lumbar puncture, blood cultures

Treatment
• treat with IV antibiotics, drainage of middle ear ± mastoidectomy

Acoustic Neuroma (Vestibular Schwannoma)

Definition
• schwannoma of the vestibular portion of CN VIII

Pathogenesis
• starts in the internal auditory canal and expands into cerebellopontine angle (CPA), compressing cerebellum and brainstem
• when associated with type 2 neurofibromatosis (NF2): bilateral acoustic neuromas, café-au-lait skin lesions, and multiple intracranial lesions

Clinical Features
• usually presents with unilateral SNHL (chronic) or tinnitus
• dizziness and unsteadiness may be present, but true vertigo is rare as tumour growth occurs slowly and thus compensation occurs
• facial nerve palsy and trigeminal (V1) sensory deficit (corneal reflex) are late complications
• risk factors: exposure to loud noise, childhood exposure to low-dose radiation, history of parathyroid adenoma

Diagnosis
• MRI with gadolinium contrast (gold standard)
• audiogram (to assess SNHL)
• poor speech discrimination relative to the hearing loss
• stapedial reflex absent or significant reflex decay
• ABR: increase in latency of the 5th wave
• vestibular tests: normal or asymmetric caloric weakness (an early sign)

Treatment
• expectant management if tumour is very small, or in elderly
• definitive management is surgical excision
• other options: gamma knife, radiation

Tinnitus

Definition
• an auditory perception in the absence of an acoustic stimuli, likely related to loss of input to neurons in central auditory pathways and resulting in abnormal firing

History
• subjective vs. objective (see Figure 14, OT7)
• continuous vs. pulsatile (vascular in origin)
• unilateral vs. bilateral
• associated symptoms: hearing loss, vertigo, aural fullness, otalgia, otorrhea

Investigations
• audiology
• if unilateral
  ▪ ABR, gadolinium enhanced MRI to exclude a retrocochlear lesion
  ▪ CT to diagnose glomus tympanicum (rare)
  ▪ MRI or angiogram to diagnose AVM
• if suspect metabolic abnormality: lipid profile, TSH

Treatment
• if a cause is found, treat the cause (e.g. drainage of middle ear effusion, embolization or excision of AVM)
• with no treatable cause: 50% will improve, 25% worsen, 25% remain the same
• avoid loud noise, ototoxic meds, caffeine, smoking
• tinnitus clinics
• identify situations where tinnitus is most bothersome (e.g. quiet times), mask tinnitus with soft music or “white noise”
• hearing aid if coexistent hearing loss
• tinnitus instrument: combines hearing aid with white noise masker
• trial of tocainamide

### Diseases of the External Ear

#### Cerumen Impaction

**Etiology**
- ear wax: a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

**Risk Factors**
- hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

**Clinical Features**
- hearing loss (conductive)
- ± tinnitus, vertigo, otalgia, aural fullness

**Treatment**
- ceruminolytic drops (bicarbonate solution, olive oil, glycerine, Cerumenol®, Cerumenex®)
- syringing
- manual debridement (by MD)

#### Exostoses

**Definition**
- bony protuberances in the external auditory canal composed of lamellar bone

**Etiology**
- possible association with swimming in cold water

**Clinical Features**
- usually an incidental finding
- if large, they can cause cerumen impaction or otitis externa

**Treatment**
- no treatment required unless symptomatic

#### Otitis Externa

**Etiology**
- bacteria (~90% of OE): *Pseudomonas aeruginosa, Pseudomonas vulgaris, E. coli, S. aureus*
- fungus: *Candida albicans, Aspergillus niger*

**Risk Factors**
- associated with swimming (“swimmer’s ear”)
- mechanical cleaning (Q-tips®), skin dermatitis, aggressive scratching
- devices that occlude the ear canal: hearing aids, headphones, etc.
- allergic contact dermatitis, dermatologic conditions (psoriasis, atopic dermatitis)

**Clinical Features**
- acute
  - pain aggravated by movement of auricle (traction of pinna or pressure over tragus)
  - otorrhea (sticky yellow purulent discharge)
  - conductive hearing loss ± aural fullness 2° to obstruction of external canal by swelling and purulent debris
  - posterior auricular lymphadenopathy
  - complicated OE exists if the pinna and/or the periauricular soft tissues are erythematos and swollen
- chronic
  - pruritus of external ear ± excoriation of ear canal
  - atrophic and scaly epidermal lining, ± otorrhea, ± hearing loss
  - wide meatus but no pain with movement of auricle
  - tympanic membrane appears normal

---

Cerumen impaction is the most common cause of conductive hearing loss for those aged 15-50 yr

Syringing

**Indications**
- Totally occlusive cerumen with pain, decreased hearing, or tinnitus

**Contraindications**
- Active infection
- Previous ear surgery
- Only hearing ear
- TM perforation

**Complications**
- Otitis externa
- TM perforation
- Trauma
- Pain
- Vertigo
- Tinnitus
- Otitis media

**Method**
- Establish that TM is intact
- Gently pull the pinna superiorly and posteriorly
- Using warm water, aim the syringe nozzle upwards and posteriorly to irrigate the ear canal

Pulling on the pinna is extremely painful in otitis externa, but is usually well tolerated in otitis media
Treatment
- clean ear under magnification with irrigation, suction, dry swabbing, and C&S
- bacterial etiology
  - antipseudomonal otic drops (e.g. ciprofloxacin) or a combination of antibiotic and steroid (e.g. Cipro HC®)
  - do not use aminoglycoside if the tympanic membrane (TM) is perforated because of the risk of ototoxicity
  - introduction of fine gauze wick (pope wick) if external canal edematous
  - ± 3% acetic acid solution to acidify ear canal (low pH is bacteriostatic)
  - systemic antibiotics if either cervical lymphadenopathy or cellulitis is present
- fungal etiology
  - repeated debridement and topical antifungals (gentian violet, Mycostatin® powder, boric acid, Locacorten®, Vioform® drops)
- ± analgesics
- chronic otitis externa (pruritus without obvious infection) → corticosteroid alone (e.g. diprosalic acid)

Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)

Definition
- osteomyelitis of the temporal bone

Epidemiology
- occurs in elderly diabetics and immunocompromised patients

Etiology
- rare complication of otitis externa
- *Pseudomonas* infection in 99% of cases

Clinical Features
- otalgia and purulent otorrhea that is refractory to medical therapy
- granulation tissue on the floor of the auditory canal

Complications
- cranial nerve palsy (most commonly CN VII>CN X>CN XI)
- systemic infection, death

Management
- imaging: high resolution temporal bone CT scan, gadolinium enhanced MRI, technetium scan
- requires hospital admission, debridement, IV antibiotics, hyperbaric O₂
- may require OR for debridement of necrotic tissue/bone

Diseases of the Middle Ear

Acute Otitis Media and Otitis Media with Effusion
- see Pediatric Otolaryngology, OT39

Chronic Otitis Media

Definition
- an ear with TM perforation in the setting of recurrent or chronic ear infections

Benign
- dry TM perforation without active infection

Chronic Serous Otitis Media
- continuous serous drainage (straw-coloured)

Chronic Suppurative Otitis Media
- persistent purulent drainage through a perforated TM
Cholesteatoma

Definition
- a cyst composed of keratinized desquamated epithelial cells occurring in the middle ear, mastoid, and temporal bone
- two types: congenital and acquired

Congenital
- presents as a “small white pearl” behind an intact tympanic membrane (anterior and medial to the malleus) or as a conductive hearing loss
- believed to be due to aberrant migration of external canal ectoderm during development
- not associated with otitis media/Eustachian tube dysfunction

Acquired (more common)
- primary cholesteatoma
  - frequently associated with retraction pockets in the pars flaccida (may lead to attic cholesteatomas which are difficult to visualize)
  - often has crusting or desquamated debris on lateral surface
- secondary cholesteatoma
  - pearly mass evident behind TM, frequently associated with marginal perforation
  - may appear as skin that have replaced the mucosa of the middle ear
- the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

Clinical Features
- history of otitis media (especially if unilateral), ventilation tubes, ear surgery
- symptoms
  - progressive hearing loss (predominantly conductive although may get sensorineural hearing loss in late stage)
  - otalgia, aural fullness, fever
- signs
  - retraction pocket in TM, may contain keratin debris
  - TM perforation
  - granulation tissue, polyp visible on otoscopy
  - malodorous, unilateral otorrhea

Complications

| Table 8. Complications of Cholesteatoma |
|--------------------------------------|------------------|
| Local                                | Intracranial     |
| Ossicular erosion: conductive hearing loss | Meningitis       |
| Inner ear erosion: SNHL, dizziness, and/or labyrinthitis | Sigmoid sinus thrombosis |
| Temporal bone infection: mastoiditis, petrositis | Intracranial abscess (subdural, epidural, cerebellar) |
| Facial paralysis                      |                  |

Investigations
- audiogram and CT scan

Treatment
- there is no conservative therapy for cholesteatoma
- surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

Mastoiditis

Definition
- infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media
- more common in children than adults

Etiology
- acute mastoiditis caused by the same organisms as AOM: *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, *S. pyogenes*, *S. aureus*, *P. aeruginosa*

Clinical Features
- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)

Mastoiditis

Definition
- infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media
- more common in children than adults

Etiology
- acute mastoiditis caused by the same organisms as AOM: *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, *S. pyogenes*, *S. aureus*, *P. aeruginosa*

Clinical Features
- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)
Treatment
• IV antibiotics with myringotomy and ventilation tubes – usually all that is required acutely
• cortical mastoidectomy
  ▪ debridement of infected tissue allowing aeration and drainage
• indications for surgery
  ▪ failure of medical treatment after 48 h
  ▪ symptoms of intracranial complications
  ▪ aural discharge persisting for 4 wk and resistant to antibiotics

Otosclerosis
Definition
• fusion of stapes footplate to oval window so that it cannot vibrate

Etiology
• autosomal dominant, variable penetrance approximately 40%
• F>M, progresses during pregnancy (hormone responsive)

Clinical Features
• progressive conductive hearing loss first noticed in teens and 20s (may progress to sensorineural hearing loss if cochlea involved)
• ± pulsatile tinnitus
• tympanic membrane normal ± pink blush (Schwartz’s sign) associated with the neovascularization of otosclerotic bone
• characteristic dip at 2000 Hz (Carhart’s notch) on audiogram (see Figure 16C, OT10)

Treatment
• monitor with serial audiograms if coping with loss
• hearing aid (air conduction, bone conduction, BAHA)
• stapedectomy or stapedotomy (with laser or drill) with prosthesis is definitive treatment

Diseases of the Inner Ear

Congenital Sensorineural Hearing Loss

Hereditary Defects
• non-syndrome associated (70%)
  ▪ often idiopathic, autosomal recessive
  ▪ connexin 26 (GJB2) most common
• syndrome associated (30%)
  ▪ Waardenburg: white forelock, heterochromia iridis (each eye different colour), wide nasal bridge and increased distance between medial canthi
  ▪ Pendred: deafness associated with thyroid gland disorders, SLC26A4 gene, enlarged vestibular aqueducts
  ▪ Treacher-Collins: first and second branchial cleft anomalies
  ▪ Alport: hereditary nephritis

Prenatal TORCH Infections
• toxoplasmosis, others (e.g. HIV, syphilis), rubella, CMV, HSV

Perinatal
• Rh incompatibility
• anoxia
• hyperbilirubinemia
• birth trauma (hemorrhage into inner ear)

Postnatal
• meningitis, mumps, measles

High Risk Factors (for hearing loss in newborns)
• low birth weight/prematurity
• perinatal anoxia (low APGARs)
• kernicterus: bilirubin >25 mg/dL
• craniofacial abnormality
• family history of deafness in childhood
• 1st trimester illness: TORCH infections
• neonatal sepsis
• ototoxic drugs
• perinatal infection, including post-natal meningitis
• consanguinity
• 50-75% of newborns with SNHL have at least one of the above risk factors and 90% of these have spent time in the NICU
• presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
• early rehabilitation improves speech and school performance

Presbycusis

Definition
• SNHL associated with aging (starting in 5th and 6th decades)

Etiology
• hair cell degeneration
• age related degeneration of basilar membrane, possibly genetic etiology
• cochlear neuron damage
• ischemia of inner ear

Clinical Features
• progressive, bilateral hearing loss initially at high frequencies, then middle frequencies
• loss of discrimination of speech especially with background noise present – patients describe people as mumbling
• recruitment phenomenon: inability to tolerate loud sounds
• tinnitus

Treatment
• hearing aid if patient has difficulty functioning, hearing loss >30-35 dB, and good speech discrimination
• ± lip reading, auditory training, auditory aids (doorbell and phone lights)

Sudden Sensorineural Hearing Loss

Clinical Features
• presents as a sudden onset of significant SNHL (usually unilateral) ± tinnitus, aural fullness
• usually idiopathic, rule out other causes
  ▪ autoimmune causes (e.g. ESR, rheumatoid factor, ANA)
  ▪ MRI to rule out tumour and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)

Treatment
• oral corticosteroids within 3 d of onset: prednisone 1 mg/kg/d for 10-14 d

Prognosis
• depends on degree of hearing loss
• 70% resolve within 10-14 d
• 20% experience partial resolution
• 10% experience permanent hearing loss

Autoimmune Inner Ear Disease

Etiology
• idiopathic
• may be associated with systemic autoimmune diseases (e.g. rheumatoid arthritis, SLE), vasculitides (e.g. GPA, polyarteritis nodosa), and allergies

Epidemiology
• most common between ages 20-50

Clinical Features
• rapidly progressive or fluctuating bilateral SNHL
• ± tinnitus, aural fullness, vestibular symptoms (e.g. ataxia, disequilibrium, vertigo)

Investigations
• autoimmune workup: CBC, ESR, ANA, rheumatoid factor

Presbycusis is the most common cause of SNHL

Sudden SNHL may easily be confused with ischemic brain events. It is important to keep a high index of suspicion especially with elderly patients presenting with sudden SNHL as well as vertigo
Treatment
- high-dose corticosteroids: treat early for at least 30 d
- consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides
- streptomycin and gentamicin (vestibulotoxic), kanamycin, and tobramycin (cochleotoxic)
- toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
- destroys sensory hair cells: outer first, inner second (therefore otoacoustic emissions are lost first)
- high frequency hearing loss develops earliest
- ototoxicity occurs days to weeks post-treatment
- must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems
- q24h dosing recommended (with amount determined by creatinine clearance)
- aminoglycoside toxicity displays saturable kinetics, therefore, once daily dosing presents less risk than divided daily doses
- duration of treatment is the most important predictor of ototoxicity
- treatment: immediately stop aminoglycosides

Salicylates
- hearing loss with tinnitus, reversible if discontinued

Antimalarials (Quinines)
- hearing loss with tinnitus
- reversible if discontinued but can lead to permanent loss

Others
- many antineoplastic agents are ototoxic (weigh risks vs. benefits)
- loop diuretics

Noise-Induced Sensorineural Hearing Loss

Pathogenesis
- 85-90 dB over months or years or single sound impulses >135 dB can cause cochlear damage
- bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as “boilermaker’s notch” on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
- speech reception not altered until hearing loss >30 dB at speech frequency, therefore considerable damage may occur before patient complains of hearing loss
- difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss
- dependent on: intensity of sound and duration of exposure
- temporary threshold shift
  ▪ when exposed to loud sound, decreased sensitivity or increased threshold for sound
  ▪ may have associated aural fullness and tinnitus
  ▪ with removal of noise, hearing returns to normal
- permanent threshold shift
  ▪ hearing does not return to previous state

Treatment
- hearing aid
- prevention
  ▪ ear protectors: muffs, plugs
  ▪ limit exposure to noise with frequent rest periods
  ▪ regular audiologic follow-up
Temporal Bone Fractures

</tbody>
</table>

- characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
- temporal bone fractures are rarely purely transverse or longitudinal (often a mixed picture)

Diagnosis
- otoscopy
- do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
- CT head
- audiology, facial nerve tests (for transverse fractures), Schirmer’s test (of lacrimation), stapedial reflexes if CN VII palsy
- if suspecting CSF leak: look for halo sign, send fluid for β-2 transferrin

Treatment
- ABCs
- medical: expectant, prevent otogenic meningitis
- surgical: explore temporal bone, indications
  - CN VII palsy (immediate and complete)
  - gunshot wound
  - depressed fracture of external auditory meatus
  - early meningitis (mastoidectomy)
  - bleeding intracranially from sinus
  - CSF otorrhea (may resolve spontaneously)

Complications
- AOM ± labyrinthitis ± mastoiditis
- meningitis/epidural abscess/brain abscess
- post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Etiology
- supranuclear and nuclear (MS, poliomyelitis, cerebral tumours)
- infranuclear

Treatment
- treat according to etiology plus provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
- facial paralysis that does not resolve with time or with medical treatment will often be referred for possible reanimation techniques to restore function
  - common reanimation techniques include
    - direct facial nerve anastomosis
    - interpositional grafts
    - anastomosis to other motor nerves
    - muscle transpositions

### Allergic Rhinitis (Hay Fever)

#### Definition
- rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
- acute-and-seasonal or chronic-and-perennial
- perennial allergic rhinitis often confused with recurrent colds

#### Etiology
- when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
- concentration of allergen in the ambient air correlates directly with the rhinitis symptoms

#### Epidemiology
- age at onset usually <20 yr
- more common in those with a personal or family history of allergies/atopy

#### Clinical Features
- nasal: obstruction with pruritus, sneezing
- clear rhinorrhea (containing increased eosinophils)
- itching of eyes with tearing
- frontal headache and pressure
- mucosa: swollen, pale, "boggy"
- seasonal (summer, spring, early autumn)
  - pollens from trees
  - lasts several weeks, disappears, and recurs following year at same time
- perennial
  - inhaled: house dust, wool, feathers, foods, tobacco, hair, mould
  - ingested: wheat, eggs, milk, nuts
  - occurs intermittently for years with no pattern or may be constantly present

#### Complications
- chronic sinusitis/polyps
- serous otitis media

#### Diagnosis
- history
- direct exam
- allergy testing

#### Treatment
- education: identification and avoidance of allergen
- nasal irrigation with saline
- antihistamines (e.g. diphenhydramine, fexofenadine)
- oral decongestants (e.g. pseudoephedrine, phenylpropanolamine)
- topical decongestant (may lead to rhinitis medicamentosa)
- other topicals: steroids (fluticasone), disodium cromoglycate, antihistamines, ipratropium bromide
- oral steroids if severe
- desensitization by allergen immunotherapy

Congestion reduces nasal airflow and allows the nose to repair itself (i.e. washes away the irritants) Treatment should focus on the initial insult rather than target this defense mechanism
Vasomotor Rhinitis

- neurovascular disorder of nasal parasympathetic system (vidian nerve) affecting mucosal blood vessels
- nonspecific reflex hypersensitivity of nasal mucosa
- caused by
  - temperature change
  - alcohol, dust, smoke
  - stress, anxiety, neurosis
  - endocrine: hypothyroidism, pregnancy, menopause
  - parasympathomimetic drugs
  - beware of rhinitis medicamentosa: reactive vasodilation due to prolonged use (>5 d) of nasal drops and sprays (Dristan*, Otrivin*)

Clinical Features
- chronic intermittent nasal obstruction, varies from side to side
- rhinorrhea: thin, watery
- mucosa and turbinates: swollen
- nasal allergy must be ruled out

Treatment
- elimination of irritant factors
- parasympathetic blocker (Atrovent* nasal spray)
- steroids (e.g. beclomethasone, fluticasone)
- surgery (often of limited lasting benefit): electrocautery, cryosurgery, laser treatment, or removal of inferior or middle turbinates
- vidian neurectomy (rarely done)
- symptomatic relief with exercise (increased sympathetic tone)

Rhinosinusitis

Pathogenesis of Rhinosinusitis
- ostial obstruction or dysfunctional cilia permit stagnant mucous and, consequently, infection
- all sinuses drain to a common prechamber under the middle meatus called the osteomeatal complex

Definition
- inflammation of the mucosal lining of the sinuses and nasal passages

Classification
- acute: <4 wk
- subacute: 4-8 wk
- chronic: >8-12 wk

Table 13. Etiologies of Rhinosinusitis

Acute Bacterial Rhinosinusitis

Definition
- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥ 2 major symptoms, at least one of the symptoms is either nasal obstruction or purulent/discoloured nasal discharge

- **major symptoms**
  - facial pain/pressure/fullness
  - nasal obstruction
  - purulent/discoloured nasal discharge
  - hyposmia/anosmia

- **minor symptoms**
  - headache
  - halitosis
  - fatigue
  - dental pain
  - cough
  - ear pain/fullness

Etiology
- bacteria: *S. pneumoniae* (35%), *H. influenzae* (35%), *M. catarrhalis*, *S. aureus*, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral is still more common
- maxillary sinus most commonly affected
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless, black or pale mucosa on examination)

Clinical Features
- sudden onset of
  - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
  - ± facial pain or pressure, hyposmia, sore throat
- persistent/worsening symptoms >5-7 d or presence of purulence for 3-4 d with high fever
- speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
- predisposing factors: viral URTI, allergy, dental disease, anatomical defects
- differentiate from acute viral rhinosinusitis (course: <10 d, peaks by 3 d)

Management
- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
- mild-moderate: INCS
- if no response within 72 h, add antibiotics
- severe: INCS + antibiotics
- antibiotics
  - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
  - if no response to 1st line antibiotics within 72 h, switch to 2nd line
  - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid inhibitors
  - adjuvant therapy (saline irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
- CT indicated only if complications are suspected

Chronic Rhinosinusitis

Definition
- inflammation of the mucosa of paranasal sinuses and nasal passages >8-12 wk
- diagnosis requiring ≥ 2 major symptoms for >8-12 wk and ≥ 1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

Etiology
- unclear etiology but the following may contribute or predispose
  - inadequate treatment of acute rhinosinusitis
  - bacterial colonization/biofilms
    - *S. aureus*, enterobacteriaceae, *Pseudomonas*, *S. pneumoniae*, *H. influenzae*, β-hemolytic streptococci
  - fungal infection (e.g. *Aspergillus*, *Zygomycetes*, *Candida*)
  - anatomic abnormality (e.g. lost ostia patency, deviated septum – predisposing factors)
  - allergy/allergic rhinitis
  - ciliary disorder (e.g. cystic fibrosis, Kartagener syndrome)
  - chronic inflammatory disorder (e.g. GPA)
  - untreated dental disease

Acute Rhinosinusitis Complications
Consider hospitalization if any of the following are suspected
- • Orbital (Chandler’s classification)
  - Periorbital cellulitis
  - Orbital cellulitis
  - Subperiosteal abscess
  - Orbital abscess
  - Cavernous sinus thrombosis
- • Intracranial
  - Meningitis
  - Abscess
  - Bony
    - Subperiosteal frontal bone abscess (“Pott’s Puffy tumour”)
    - Osteomyelitis
  - Neurologic
    - Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypoesthesia)
    - Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)
Clinical Features (similar to acute, but less severe)
- chronic nasal obstruction
- purulent anterior/posterior nasal discharge
- facial congestion/fullness
- facial pain/pressure
- hyposmia/anosmia
- halitosis
- chronic cough
- maxillary dental pain

Management
- identify and address contributing or predisposing factors
- obtain CT or perform endoscopy
- if polyps present: INCS, oral steroids ± antibiotics (if signs of infection), refer to otolaryngologist/H&N surgeon
- if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
- antibiotics for 3-6 wk
  - amoxillin-clavulanic acid inhibitors, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin, Flagyl® (metronidazole)
- surgery if medical therapy fails or fungal sinusitis: FESS, balloon sinoplasty

Complications
- same as acute sinusitis, mucocele

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)
1. Superior posterior septum
   - internal carotid → ophthalmic → anterior/posterior ethmoidal
2. Posterior septum
   - external carotid → internal maxillary → sphenopalatine artery → nasopalatine
3. Lower anterior septum
   - external carotid → facial artery → superior labial artery → nasal branch
   - external carotid → internal maxillary → descending palatine → greater palatine
- these arteries all anastomose to form Kiesselbach’s plexus, located at Little’s area (anterior-inferior portion of the cartilaginous septum)
- bleeding from above middle turbinate is internal carotid, and from below is external carotid

Table 14. Etiology of Epistaxis

Investigations
- CBC, PT/PTT (if indicated)
- x-ray, CT as needed

Treatment
- locate bleeding and achieve hemostasis
1. ABCs
- lean patient forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 20 min on cartilaginous part of nose (not bony pyramid)
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross-match blood

2. Determine Site of Bleeding
- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant (i.e. Otrivin®) to help identify area of bleeding (often anterior septum)
- if suspicious bleeding disorder, coagulation workup (platelet number and platelet function assay)

3. Control the Bleeding
- first line topical vasoconstrictors (Otrivin®)
- if first line fails and bleeding adequately visualized, cauterize with silver nitrate
- do not cauterize both sides of the septum at one time due to risk of septal perforation from loss of septal blood supply

A. Anterior hemorrhage treatment
- if failure to achieve hemostasis with cauterization
- place anterior pack* with half inch Vaseline®-soaked ribbon gauze strips layered from nasal floor toward nasal roof extending to posterior choanae or lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel®) for 2-3 d
- can also attempt packing with Merocel® or nasal tampons of different shapes
- can also apply Floseal® (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail

B. Posterior hemorrhage treatment
- if unable to visualize bleeding source, then usually posterior source
- place posterior pack* using a Foley catheter, gauze pack, or Epistat® balloon
- subsequently, layer anterior packing bilaterally
- admit to hospital with packs in for 3-5 d
- watch for complications: hypoxemia (nasopulmonic reflex), toxic shock syndrome (Rx: remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration

C. If anterior/posterior packs fail to control epistaxis
- ligation or embolization of culprit arterial supply by interventional radiology
- ± septoplasty
- * antibiotics for any posterior pack or any pack left for >48 h because of risk of toxic shock syndrome

4. Prevention
- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of HTN and coagulopathies

---

**Hoarseness**

Definitions
- hoarseness: change in voice quality, ranging from voice harshness to voice weakness; reflects abnormalities anywhere along the vocal tract from oral cavity to lungs
- dysphonia: a general alteration in voice quality
- aphasis: no sound emanates from vocal folds

**Acute Laryngitis**

Definition
- <2 wk inflammatory changes in laryngeal mucosa

Etiology
- viral: influenza, adenovirus
- bacterial: Group A Streptococcus
- mechanical acute voice strain → submucosal hemorrhage → vocal cord edema → hoarseness
- environmental: toxic fume inhalation

Clinical Features
- URTI symptoms, hoarseness, aphasis, cough attacks, ± dyspnea
- true vocal cords erythematous/edematous with vascular injection and normal mobility

Treatment
- usually self-limited, resolves within ~1 wk
- voice rest
- humidification
- hydration

If hoarseness present for >2 wk in a smoker, laryngoscopy must be done to rule out malignancy

Vocal Cord Paralysis

Unilateral: affected cord lies in the parmedian position, inadequate glottic closure during phonation → weak, breathy voice. Usually mediates with time whereby phonation and aspiration improve. Treatment options include voice therapy, injection laryngoplasty (Radiesse), medialization using silastic block

Bilateral: cords rest in midline therefore voice remains good but respiratory function is compromised and may present as stridor. If no respiratory issues, may monitor closely and wait for improvement. If respiratory issues, intubate and will likely require a tracheotomy
• avoid irritants (e.g. smoking)
• treat with antibiotics if there is evidence of coexistent bacterial pharyngitis

### Chronic Laryngitis

**Definition**
• >2 wk inflammatory changes in laryngeal mucosa

**Etiology**
• repeated attacks of acute laryngitis
• chronic irritants (dust, smoke, chemical fumes)
• chronic voice strain
• chronic rhinosinusitis with postnasal drip
• chronic EtOH use
• esophageal disorders: GERD, Zenker’s diverticulum, hiatus hernia
• systemic: allergy, hypothyroidism, Addison's disease

**Clinical Features**
• chronic dysphonia: rule out malignancy
• cough, globus sensation, frequent throat clearing 2º to GERD
• laryngoscopy: cords erythematous, thickened with ulceration/granuloma formation, and normal mobility

**Treatment**
• remove offending irritants
• treat related disorders (e.g. antisecretory therapy for GERD)
• speech therapy with voice rest
• ± antibiotics ± steroids to decrease inflammation
• laryngoscopy to rule out malignancy

### Vocal Cord Polyps

**Definition**
• structural manifestation of vocal cord irritation
• acutely, polyp forms 2º to capillary damage in the subepithelial space during extreme voice exertion

**Etiology**
• most common benign tumour of vocal cords
• voice strain (muscle tension dysphonia)
• laryngeal irritants (GERD, allergies, tobacco)

**Epidemiology**
• 30-50 yr of age
• M>F

**Clinical Features**
• hoarseness, aphonia, cough attacks ± dyspnea
• pedicled or sessile polyp on free edge of vocal cord
• typically polyp asymmetrical, soft, and smooth
• more common on the anterior 1/3 of the vocal cord
• intermittent respiratory distress with large polyps

**Treatment**
• avoid irritants
• endoscopic laryngeal microsurgical removal if persistent or if high risk of malignancy

### Vocal Cord Nodules

**Definition**
• vocal cord callus
• i.e. “screamer’s or singer’s nodules”

**Etiology**
• early nodules occur 2º to submucosal hemorrhage
• mature nodules result from hyalinization which occurs with long-term voice abuse
• chronic voice strain
• frequent URTI, smoke, EtOH

---

**Vocal Cords: Polyps vs. Nodules**

<table>

<td>Surgical excision if persistent or in presence of risk factors for laryngeal cancer</td>
<td>Surgical excision as last resort</td>
</tr>
</tbody>
</table>
Epidemiology
- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features
- hoarseness worst at end of day
- on laryngoscopy
  - often bilateral
  - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment
- voice rest
- hydration
- speech therapy
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomas

Etiology
- HPV types 6, 11
- possible hormonal influence, possibly acquired during delivery

Epidemiology
- biphasic distribution: 1) birth to puberty (most common laryngeal tumour) and 2) adulthood

Clinical Features
- hoarseness and airway obstruction
- can seed into tracheobronchial tree
- highly resistant to complete removal
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation
- laryngoscopy shows wart-like lesions in supraglottic larynx and trachea

Treatment
- microdebridement or CO₂ laser
- adjuvants under investigation: interferon, cidofovir, acyclovir
- HPV vaccine may prevent/decrease the incidence but more research is needed

Laryngeal Carcinoma

- see Neoplasms of the Head and Neck, OT35

Salivary Glands

Sialadenitis

Definition
- inflammation of salivary glands

Etiology
- viral most common (mumps)
- bacterial causes: S. aureus, S. pneumoniae, H. influenzae
- obstructive vs. non-obstructive
- obstructive infection involves salivary stasis and bacterial retrograde flow

Predisposing Factors
- HIV
- anorexia/bulimia
- Sjögren's syndrome
- Cushing's, hypothyroidism, DM
- hepatic/renal failure
- meds that increase stasis: diuretics, TCAs, β-blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)
Clinical Features
- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- ± fever
- ± leukocytosis
- ± suppurative drainage from punctum of the gland

Investigations
- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

Treatment
- bacterial: treat with cloxacillin ± abscess drainage, sialogogues
- viral: no treatment

Sialolithiasis

Definition
- ductal stone (mainly hydroxyapatite) in adults, sand/sludge in children, leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

Risk Factors
- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, diabetes, EtOH, hypercalcemia, psychiatric medication)

Clinical Features
- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

Investigations
- U/S ± sialogram

Treatment
- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- if calculus is within the gland parenchyma, the whole gland must be excised

Salivary Gland Neoplasms

Etiology
- anatomic distribution
  - parotid gland: 70-85%
  - submandibular gland: 8-15%
  - sublingual gland: 1%
  - minor salivary glands, most concentrated in hard palate: 5-8%
- malignant (see Table 15, OT32 and Table 16, OT36)
- benign
  - benign mixed (pleomorphic adenoma): 80%
  - Warthin's tumour (5-10% bilateral, M>F): 10%
  - cysts, lymph nodes and adenomas: 10%
  - oncocytoma: <1%

Epidemiology
- 3-6% of all head and neck neoplasms in adults
- mean age at presentation: 55-65
- M=F
**Parotid Gland Neoplasms**

**Clinical Features**
- 80% benign (pleomorphic adenoma: most common), 20% malignant (mucoepidermoid: most common)
- if bilateral, suggests benign process (Warthin's tumour, Sjögren's, bulimia, mumps) or possible lymphoma
- facial nerve involvement (i.e. facial paralysis): increases risk of malignancy

**Investigations**
- FNA biopsy
- CT, U/S, or MRI to determine extent of tumour

**Treatment**
- treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
  - pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
  - superficial tumour
    - superficial parotidectomy above plane of CN VII ± radiation
  - incisional biopsy contraindicated
  - deep lesion
    - near-total parotidectomy sparing as much of CN VII as possible
    - if CN VII involved then it is removed and cable grafted
  - complications of parotid surgery
    - haematoma, infection, salivary fistula, temporary facial paresis, Frey’s syndrome (gustatory sweating)

**Prognosis**
- benign: excellent, <5% of pleomorphic adenomas may recur
- malignant: dependent on stage and type of malignancy (see Table 16, OT36)

**Neck Masses**

**Approach to a Neck Mass**
- ensure that the neck mass is not a normal neck structure (hyoid, transverse process of C1 vertebra, prominent carotid bulb)
- any neck mass persisting for >2 wk should be investigated for possible neoplastic causes

**Table 15. Acquired Causes of Neck Lumps According to Age**

<table>
<thead>
<tr>
<th>Age (yr)</th>
<th>Possible Causes of Neck Lump</th>

<td>1. Inflammatory 2. Congenital 3. Neoplastic</td>
</tr>
<tr>
<td>&gt;40</td>
<td>1. Neoplastic 2. Inflammatory 3. Congenital</td>
</tr>
</tbody>
</table>

**Differential Diagnosis**
- congenital
  - lateral (branchial cleft cyst, lymphatic/venous/venolymphatic malformation)
  - midline (thyroglossal duct cyst, dermoid cyst, laryngocele)
- infectious/inflammatory
  - reactive lymphadenopathy (2nd to tonsillitis, pharyngitis)
  - infectious mononucleosis
  - Kawasaki, Kikuchi, Kimura, Cat Scratch, Castleman’s
  - HIV
  - salivary gland calculi, sialadenitis
- thyroiditis
- granulomatous disease
- mycobacterial infections
- sarcoidosis
- neoplastic
  - lymphoma
  - salivary gland tumours
  - thyroid tumours
  - metastatic malignancy (“unknown primary”)

**DDx Parotid Tumour**

<table>
<thead>
<tr>
<th>Benign</th>
<th>Malignant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pleomorphic adenoma</td>
<td>Mucoepidermoid carcinoma</td>
</tr>
<tr>
<td>Warthin’s tumour (more common in men)</td>
<td>Salivary gland tumours</td>
</tr>
<tr>

<td>Thyroid tumours</td>
</tr>
<tr>
<td>Oncocytoma</td>
<td>Metastatic malignancy (“unknown primary”)</td>
</tr>
</tbody>
</table>

**Frey’s syndrome** is a post-operative complication characterized by gustatory sweating. It is due to aberrant innervation of cutaneous sweat glands by parasympathetic nerve fibres that are divided during surgery.
**Evaluation**

**Investigations**
- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
- laboratory investigations
  - WBC: infection vs. lymphoma
  - Mantoux TB test
  - thyroid function tests and scan
- imaging
  - neck U/S
  - CT scan
  - angiography: vascularity and blood supply to mass
- biopsy: for histologic examination
  - FNA: least invasive
  - needle biopsy
  - open biopsy: for lymphoma
- identification of possible primary tumour (rule out a metastatic lymph node from an “unknown primary”)
  - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
  - biopsy of normal tissue of nasopharynx, tonsils, base of tongue, and hypopharynx
  - primary identified 95% of time → stage and treat
  - primary occult 5% of time: excisional biopsy of node for histologic diagnosis → manage with radiotherapy and/or neck dissection (squamous cell carcinoma)

**Congenital Neck Masses**

**Branchial Cleft Cysts/Fistula**

**Embryology**
- at the 6th wk of development, the 2nd branchial arch grows over the 3rd and 4th arches and fuses with the neighbouring caudal pre-cardial swelling forming the cervical sinus
- 3 types of malformations
  1. branchial fistula: persistent communication between skin and GI tract
  2. branchial sinus: blind-ended tract opening to skin
  3. branchial cyst: persistent cervical sinus with no external opening

**Clinical Features**
- 2nd branchial cleft malformations most common
  - sinuses and fistulae present in infancy as a small opening anterior to the sternocleidomastoid muscle
  - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following a URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area or on face over angle of mandible
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract leading usually to the left pyriform sinus
- there is controversy whether or not 4th branchial cleft anomalies exist, as they may be remnants of the thyrothymic axis

**Treatment**
- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal (antibiotics may be required)
Thyroglossal Duct Cysts

Embryology
- thyroid originates as ventral midline diverticulum at base of tongue caudal to junction of 3rd and 4th branchial arches (foramen cecum) and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of tract

Clinical Features
- usually presents in childhood or during 20-40s as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion

Treatment
- pre-operative antibiotics to reduce inflammation (infection before surgery is a well described cause of recurrence)
- small potential for neoplastic transformation so complete excision of cyst and tissue around tract up to foramen cecum at base of tongue with removal of central portion of hyoid bone (Sistrunk procedure) recommended
**Lymphatic Malformation**

**Definition**
- lymphatic malformation arising from vestigial lymph channels of neck

**Clinical Features**
- usually present by age 2
- can be macrocystic (composed of large thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection causes a sudden increase in size

**Treatment**
- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several months after infection
- macrocystic lesions can be treated by sclerotherapy or surgical excision
- microcystic lesions are difficult to treat, but can be debulked

---

**Neoplasms of the Head and Neck**

**Pre-Malignant Disease**
- **leukoplakia**
  - hyperkeratosis of oral mucosa
  - risk of malignant transformation 5-20%
- **erythroplakia**
  - red superficial patches adjacent to normal mucosa
  - commonly associated with epithelial dysplasia
  - associated with carcinoma in situ or invasive tumour in 40% of cases
- **dysplasia**
  - histopathologic presence of mitoses and prominent nucleoli
  - involvement of entire mucosal thickness = carcinoma in situ
  - associated progression to invasive cancer in 15-30% of cases

**Investigations**
- initial metastatic screen includes CXR
- scans of liver, brain, and bone only if clinically indicated
- CT scan is superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI is superior to discriminate tumour from mucus and to detect bone marrow invasion
- ± PET scans

**Treatment**
- treatment depends on
  - histologic grade of tumour
  - stage
  - physical and psychological health of patient
  - facilities available
  - expertise and experience of the medical and surgical oncology team
- in general
  - 1st surgery for malignant oral cavity tumours with radiotherapy reserved for salvage or poor prognostic indicators
  - 1st radiotherapy for nasopharynx, oropharynx, hypopharynx, larynx malignancies with surgery reserved for salvage
  - palliative chemotherapy for metastatic or incurable disease
  - concomitant chemotherapy increases survival in advanced disease
  - chemotherapy has a role as induction therapy prior to surgery and radiation
  - panendoscopy to detect primary disease when lymph node metastasis is identified
  - anti-EGFR treatment (cetuximab, panitumumab) has a role as concurrent therapy with radiation for SCC of the head and neck (for advanced local and regional disease)

**Prognosis**
- synchronous tumours occur in 9-15% of patients
- late development of 2nd primary most common cause of post-treatment failure after 36 mo

* B symptoms = fever, night sweats, chills, weight loss >10% in 6 mo  ** CHOP = cyclophosphamide, adriamycin, vincristine, prednisone

**Approach to Thyroid Nodule**

- all patients with thyroid nodules require evaluation of serum TSH and ultrasound
- any nodule >5 mm with suspicious sonographic features (particularly microcalcifications) should undergo FNA
- any nodule >1 cm should undergo FNA
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule

*US findings: cystic: risk of malignancy <1%; solid: risk of malignancy ~10%; solid with cystic components: risk of malignancy same as if solid
Acute Otitis Media

Definition
- all of: presence of middle ear effusion (MEE); presence of middle ear inflammation (MEI); acute onset of symptoms of MEE and MEI

Epidemiology
- most frequent diagnosis in sick children visiting clinicians’ offices and most common reason for antibiotic administration
- peak incidence between 6-15 mo; ~85% of children have >1 episode by 3 yr old
- seasonal variability: peaks in winter

Etiology
- primary defect causing AOM: Eustachian tube dysfunction/obstruction → stasis/colonization by pathogens
- bacterial: S. pneumoniae, non-typable H. influenzae, M. catarrhalis, Group A Streptococcus, S. aureus
- viral: RSV, influenza, parainfluenza, adenovirus
- commonly due to bacterial/viral co-infection

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - swelling of tubal mucosa
  - upper respiratory tract infection (URTI)
  - allergic rhinitis
  - chronic rhinosinusitis
- obstruction/infiltration of Eustachian tube ostium
  - tumour: nasopharyngeal carcinoma (adults)
  - adenoid hypertrophy (not due to obstruction but by maintaining a source of infection)
  - barotrauma (sudden changes in air pressure)
- inadequate tensor palati function: cleft palate (even after repair)
- abnormal Eustachian tube
  - Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
- disruption of action of
  - cilia of Eustachian tube: Kartagener’s syndrome
  - mucus secreting cells
  - capillary network that provides humoral factors, PMNs, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, cystic fibrosis

Risk Factors
- non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race, and ethnicity
- modifiable: lack of breastfeeding, day care attendance, household crowding, exposure to cigarette smoke and air pollution, pacifier use

Pathogenesis
- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers
  - ear-tugging (this alone is not a good indicator of pathology)
  - hearing loss, balance disturbances (rare)
  - irritable, poor sleeping
  - vomiting and diarrhea
  - anorexia
- otoscopy of TM
  - hyperemia
  - bulging, pus may be seen behind TM
  - loss of landmarks: handle and long process of malleus not visible

Clinical Assessment of AOM in Pediatrics
JAMA 2010;304:2161-2169
In assessment of AOM in pediatrics, ear pain is the most useful symptom with a likelihood ratio (LR) between 3.0-7.3. Useful otoscopic signs include erythematous (LR 8.4, 95% CI 7-11), cloudy (LR 34, 95% CI 28-42), bulging (LR 51, 95% CI 36-73), and immobile tympanic membrane (LR 31, 95% CI 26-37) on pneumatic otoscopy.
Diagnosis

- history
  - acute onset of otalgia or ear tugging in a preverbal child, otorrhea, decreased hearing
  - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, N/V, and diarrhea
- physical
  - febrile
  - MEE on otoscopy: immobile tympanic membrane, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
  - MEI on otoscopy: bulging TM with marked discoulouration (hemorrhagic, red, grey, or yellow)

Management

- observation for 48-72 h without antimicrobials may be appropriate since >80% of AOM in children resolve spontaneously
- criteria for watchful waiting approach
  - child is >6 mo old
  - child does not have immunodeficiency, chronic cardiac or pulmonary disease, anatomical abnormalities of the head or neck, a history of complicated otitis media (suppurative complications of chronic perforation) or Down syndrome
  - the illness is not severe – otalgia appears to be mild and fever is <39°C in the absence of antipyretics
  - parents are capable of recognizing signs of worsening illness and can readily access medical care if the child does not improve
  - antimicrobials are indicated if child does not meet the criteria for watchful waiting or does not improve/worsens during observation
- maintain hydration
- symptomatic relief: acetaminophen, ibuprofen
- referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections

Treatment

- antimicrobial agents for AOM
  - 1st line treatment (no penicillin allergy)
    - amoxicillin: 75 mg/kg/d to 90 mg/kg/d divided 3x/d
  - 2nd line treatment
    - cefprozil: 30 mg/kg/d divided 2x/d
    - cefuroxime axetil: 30 mg/kg/d divided 2x/d
    - ceftriaxone: 50 mg/kg intramuscularly (or intravenously) x 1 dose
    - azithromycin: 10 mg/kg OD x 1 dose, then 5 mg/kg OD x 4 doses
    - clarithromycin: 15 mg/kg/d divided 2x/d
  - if initial therapy fails (i.e. no symptomatic improvement after 2-3 d)
    - amoxicillin-clavulanate: 90 mg/kg/d amoxicillin, 6.4 mg/kg/d clavulanate divided 2x/d for 10 d
  - if AOM-related symptoms do not resolve with amoxicillin/clavulanate, a course of ceftriaxone 50 mg/kg/d intramuscularly (or intravenously) 1/d x 3 doses could be considered

Complications

- extracranial
  - hearing loss and speech delay (secondary to persistent MEE), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labrynthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction, persistent effusion (often leading to hearing loss)
- intracranial
  - meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis, facial nerve paralysis
- other
  - mastoiditis, labyrinthitis, sigmoid sinus thrombophlebitis

Otitis Media with Effusion

Definition

- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology

- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- follows AOM frequently in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%
Risk Factors
• same as AOM

Clinical Features
• conductive hearing loss ± tinnitus
  ▫ confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
• fullness – blocked ear
• ± pain, low grade fever
• otoscopy of tympanic membrane
  ▫ discolouration – amber or dull grey with “glue” ear
  ▫ meniscus fluid level behind TM
  ▫ air bubbles
  ▫ retraction pockets/TM atelectasis
  ▫ most reliable finding with pneumotoscopy is immobility

Treatment
• expectant: 90% resolve by 3 mo
• document hearing loss with audiogram
• no clinical evidence that antihistamines, decongestants, or antibiotics clear disease faster
• surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
• ventilation tubes to equalize pressure and drain ear

Complications of Otitis Media with Effusion
• hearing loss, speech delay, learning problems in young children
• chronic mastoiditis
• ossicular erosion
• cholesteatoma especially when retraction pockets involve pars flaccida
• retraction of tympanic membrane, atelectasis, ossicular fixation

Adenoid Hypertrophy

• size peaks at age 5 and resolves by age 12
• increase in size with repeated URTI and allergies

Clinical Features
• nasal obstruction
  ▫ adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
  ▫ history of hypernasal voice and snoring
  ▫ long-term mouth breather; minimal air escape through nose
• choanal obstruction
  ▫ chronic rhinosinusitis/rhinitis
  ▫ obstructive sleep apnea
• chronic inflammation
  ▫ nasal discharge, post-nasal drip, and cough
  ▫ cervical lymphadenopathy

Diagnosis
• enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
• enlarged adenoid shadow on lateral soft tissue x-ray

Complications
• Eustachian tube obstruction leading to serous otitis media
• interference with nasal breathing, necessitating mouth-breathing
• malocclusion
• sleep apnea/respiratory disturbance
• orofacial developmental abnormalities

Adenoidectomy

Indications for Adenoidectomy
• chronic upper airway obstruction with sleep disturbance/apnea ± cor pulmonale
• chronic nasopharyngitis resistant to medical treatment
• chronic serous otitis media and chronic suppurrative otitis media (with 2nd set of tubes)
• recurrent acute otitis media resistant to antibiotics
• suspicion of nasopharyngeal malignancy
• persistent rhinorrhea secondary to nasal obstruction
Contraindications
• uncontrollable coagulopathy
• recent pharyngeal infection
• conditions that predispose to velopharyngeal insufficiency (cleft palate, impaired palatal function, or enlarged pharynx)

Complications
• bleeding, infection
• velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
• scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition
• spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology
• peak incidence between 2-8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology
• due to a combination of anatomic and neuromuscular factors
  ▪ adenotonsillar hypertrophy
  ▪ craniofacial abnormalities
  ▪ neuromuscular hypotonia (i.e. cerebral palsy, Down syndrome)
  ▪ obesity

Clinical Features
• heavy snoring, mouth breathing, pauses or apnea, enuresis, excessive daytime sleepiness, behavioural/learning problems, diagnosis of ADHD, morning headache, failure to thrive

Investigations
• flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
• polysomnography (apnea-hypopnea index >1/h considered abnormal)

Treatment
• surgical: bilateral tonsillectomy and adenoidectomy
• nonsurgical: CPAP, BiPAP, sleep hygiene

Acute Tonsillitis
• see Pediatrics, P58

Peritonsillar Abscess (Quinsy)

Definition
• cellulitis of space behind tonsillar capsule extending onto soft palate leading to abscess

Etiology
• bacterial: Group A strep (GAS) (50% of cases), S. pyogenes, S. aureus, H. influenzae, and anaerobes

Epidemiology
• can develop from acute tonsillitis with infection spreading into plane of tonsillar bed
• unilateral
• most common in 15-30 yr age group

Clinical Features
• fever and dehydration
• sore throat, dysphagia, and odynophagia
• extensive peritonsillar swelling but tonsil may appear normal
• edema of soft palate
• uvular deviation
• trismus (due to irritation and reflex spasm of the medial pterygoid)
• dysphonia (edema → failure to elevate palate) 2º to CN X involvement
• unilateral referred otalgia
• cervical lymphadenitis

Quinsy Triad
• Trismus
• Uvular deviation
• Dysphonia ("hot potato voice")
Complications
- aspiration pneumonia 2º to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

Treatment
- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for Bacteroides
- consider tonsillectomy after second episode

Other Sources of Parapharyngeal Space Infections
- pharyngitis
- acute suppurative parotitis (see Salivary Glands, OT30)
- AOM
- mastoiditis (Bezold's abscess)
- odontogenic infection

Tonsillectomy

Absolute Indications
- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, obstructive sleep apnea, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, squamous cell carcinoma)
- orofacial/dental deformity
- hemorrhagic tonsillitis

Relative Indications (To Reduce Disease Burden)
- recurrent throat infection with a frequency of at least 7 episodes in the past year, at least 5 episodes per year for 2 yr, or at least 3 episodes per year for 3 yr, with documentation in the medical record for each episode of sore throat and 1 or more of the following: temperature >38.3°C, cervical adenopathy, tonsillar exudate, or positive test for Group A β-hemolytic streptococcus (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of calcified material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

Relative Contraindications
- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuro-muscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

Complications
- hemorrhage: early (within 24 h); delayed (within 7-10 d)
- odynophagia and/or otalgia; dehydration 2º to odynophagia
- infection
- atlantoaxial subluxation (Grisel's syndrome) - rare

Airway Problems in Children

Differential Diagnosis by Age Group

Neonates (Obligate Nose Breeders)
- extralaryngeal
  - choanal atresia (e.g. CHARGE syndrome)
  - nasopharyngeal dermoid, glioma, encephalocele
  - glossoptosis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma
- laryngeal
  - laryngomalacia: most common cause of stridor in children
  - laryngocele
- vocal cord palsy (due to trauma or Arnold-Chiari malformation)
- glottic web
- subglottic stenosis
- laryngeal cleft
- tracheal
  - tracheoesophageal fistula
  - tracheomalacia
  - vascular rings

**2-3 Months**
- congenital
  - laryngomalacia
  - vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
  - laryngeal papilloma
- acquired
  - subglottic stenosis: post-intubation
  - tracheal granulation: post-intubation
  - tracheomalacia: post-tracheotomy and TEF repair

**Infants – Sudden Onset**
- foreign body aspiration
- croup
- bacterial tracheitis
- caustic ingestion
- epiglottitis

**Children and Adults**
- infection
  - Ludwig's angina
  - peritonsillar/parapharyngeal abscess
  - retropharyngeal abscess
- neoplastic
  - squamous cell carcinoma (SCC) (adults): larynx, hypopharynx
  - retropharyngeal: lymphoma, neuroblastoma
  - nasopharyngeal: carcinoma, rhabdomyosarcoma
- allergic
  - angioneurotic edema
  - polyps (suspect cystic fibrosis in children)
- trauma
  - laryngeal fracture, facial fracture
  - burns and lacerations
  - post-intubation
  - caustic ingestion
- congenital
  - lingual thyroid/tonsil

---

**Signs of Airway Obstruction**

**Stridor**
- note quality, timing (inspiratory or expiratory)
- body position important
  - lying prone: subglottic hemangioma, double aortic arch
  - lying supine: laryngomalacia, glossoptosis
- site of stenosis
  - vocal cords or above: inspiratory stridor
  - subglottis and extrathoracic trachea: biphasic stridor
  - distal tracheobronchial tree: expiratory stridor

**Respiratory Distress**
- nasal flaring
- supraclavicular and intercostal indrawing
- sternal retractions
- use of accessory muscles of respiration
- tachypnea
- cyanosis
- altered LOC
Feeding Difficulty and Aspiration
- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft → aspiration pneumonia
- TEF

**Acute Laryngotracheobronchitis (Croup)**
- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining and associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

**Etiology**
- viral: parainfluenzae I (most common), II, III, influenza A and B, RSV

**Clinical Features**
- age: 4 mo-5 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea-lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- "steeple-sign" on AP x-ray of neck
- if recurrent croup, think subglottic stenosis

**Treatment**
- racemic epinephrine via MDI q1-2h, prn (only if in respiratory distress)
- systemic corticosteroids (e.g. dexamethasone, prednisone)
- adequate hydration
- close observation for 3-4 h
- intubation if severe
- hospitalize if poor response to steroids after 4 h and persistent stridor at rest
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, consider bronchoscopy several weeks after acute episode settles to rule out underlying subglottic stenosis

**Acute Epiglottitis**
- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

**Etiology**
- *H. influenzae* type b
- relatively uncommon condition due to Hib vaccine

**Clinical Features**
- any age, most commonly 1-4 yr
- rapid onset
- toxic-looking, fever, anorexia, restlessness
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up ("tripod" posture), open mouth, drooling, tongue protruding, sore throat, dysphagia

**Investigations and Management**
- investigations and physical exam may lead to complete obstruction, thus preparations for intubation or tracheotomy must be made prior to any manipulation
- stat ENT/anesthesia consult(s)
- WBC (elevated), blood and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable)

**Treatment**
- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis
Subglottic Stenosis

Congenital
• diameter of subglottis <4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage)

Acquired
• following prolonged, repeated, or traumatic intubation
  ▪ most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long-term intubation as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
  ▪ subglottic stenosis is related to duration of intubation and pressure of the endotracheal tube cuff
• can also be due to foreign body, infection (e.g. TB, diphtheria, syphilis), or chemical irritation

Clinical Features
• biphasic stridor
• respiratory distress
• recurrent/prolonged croup

Diagnosis
• rigid laryngoscopy and bronchoscopy

Treatment
• if soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
• if firm stenosis: laryngotracheoplasty

Laryngomalacia
• short aryepiglottic folds, omega-shaped epiglottis, pendulous mucosa
• caused by indrawing of supraglottis on inspiration leading to laryngopharyngeal reflux of acid

Clinical Features
• high-pitched inspiratory stridor at 1-2 wk
• constant or intermittent and more pronounced supine and following URTI
• usually mild but when severe can be associated with cyanosis or feeding difficulties, leading to failure to thrive

Treatment
• observation is usually sufficient as symptoms spontaneously subside by 12-18 mo in >90% of cases
• if severe, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested
• usually stuck at cricopharyngeus
• coins, toys, batteries (emergency)
• presents with drooling, dysphagia, stridor if very large

Aspirated
• usually stuck at right mainstem bronchus
• peanuts, carrot, apple core, popcorn, balloons
• presentation
  ▪ stridor if lodged in trachea
  ▪ unilateral “asthma” if bronchial, therefore often misdiagnosed as asthma
  ▪ if totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Diagnosis and Treatment
• any patient with suspected foreign body should be kept NPO immediately
• inspiration-expiration chest x-ray (if patient is stable)
• bronchoscopy or esophagoscopy with removal
• rapid onset, not necessarily febrile or elevated WBC
**Deep Neck Space Infection**

- most commonly arise from an infection of the mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
- often a rapid onset and may progress to fatal complications

**Etiology**
- usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

**Clinical Features**
- sore throat or pain and trismus
- dysphagia and odynophagia
- stridor and dyspnea
- late findings may include dysphonia and hoarseness
- swelling of the face and neck, erythema
- asymmetry of the oropharynx with purulent oral discharge
- lymphadenopathy

**Diagnosis**
- lateral cervical view plain radiograph
- CT
- MRI

**Treatment**
- secure the airway
- surgical drainage
- maximum doses of IV systemic antimicrobials regimens according to the site of infection

Primary Care

Visit Overview

- schedule
  - newborn (within 1 wk post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
  - annually between age 2-5; every 1-2 years between age 6-18
- content
  - history and physical exam including growth, development, and nutrition
  - routine immunizations
  - counselling and anticipatory guidance

IM = intramuscular; PO = per oral; SC = subcutaneous

Available at: http://www.phac-aspc.gc.ca/publicat/cig-gci/

According to the CDC, the weight of currently available scientific evidence does not support the hypothesis that MMR vaccine causes either autism or IBD. The landmark paper linking autism to the MMR vaccine (Lancet 1998;351:637-641) was retracted due to false claims in the article (Lancet 2010;375:648).

**Table 2. Publicly Funded Immunization Schedule for Ontario, August 2011 (continued)**

- **Injection site**
  - Infants (<12 mo): anterolateral thigh
  - Children: deltoid, subcutaneous tissue of the upper triceps area of the arm (IM injections should be given at 90° angle; SC injections should be given at 45° angle)

- **Timing of injection**
  - Varicella and MMR vaccines given at either the same visit or separated by >4 wk (MMRV at 4–6 yr)
  - Hepatitis B vaccine given in 3 doses of 0.5 mL (0, 1, 6 mo) either at school in grade 7 (2 adult doses of 1 mL one month apart for teens) (Ontario) or at birth if at increased risk (i.e. endemic country, mother or household contact HBsAg positive)
  - HPV-4 vaccine given in 3 doses (0, 2, 6 mo) to grade 8 females in Ontario schools

**Adverse Reactions**

- Local: injection site reactions
- Systemic: fever, rash, irritability

**Contraindications**

- Moderate/severe illness: contraindication
- Allergy to vaccine component
- No need to delay vaccination for mild URI

- Any Vaccine
  - Local: injection site reactions
  - Systemic: fever, rash, irritability
  - Allergic: urticaria, rhinitis, anaphylaxis

**Vaccination in Cases of Asplenia or Hyposplenia**

- Should receive all routine immunizations, including the yearly influenza vaccine
- No vaccines are contraindicated
- Susceptible to infection by encapsulated bacteria (S. pneumoniae, H. influenzae, N. meningitidis), so must add:
  - Meningococcal C-Conjugate at age >2 yr + Quadrivalent Men-P-ACYW at least 2 wk later
  - Booster of Men-P-ACYW q2-yr
  - Pneumococcal polysaccharide vaccine (Pneu-P-23) at age >2 yr
  - Single booster of Pneu-P-23 at age >3 yr
  - Consider single booster HB at age >5 yr

**Safety and Efficacy of an Attenuated Vaccine Against Severe Rotavirus Gastroenteritis**

- **Study:** Randomized, double-blind, phase 3 trial.
- **Patients:** 61,225 healthy infants from Latin America and Finland.
- **Intervention:** Two oral doses of HRV vaccine vs. placebo at 2 and 4 mo of age.
- **Results:** The vaccine is 85% efficacious against severe rotavirus gastroenteritis and hospitalizations associated with gastroenteritis and 100% efficacious against more severe gastroenteritis.

**Growth and Development**

- **Growth**
  - Growth is not linear
  - Most rapid growth during first 2 yr and at puberty
  - Tissues grow at different times
    - First 2 yr = CNS; mid-childhood = lymphoid tissue; puberty = gonads
  - Measurement of growth
    - Premature infants (<37 wk) use corrected GA until age 2
    - Body proportion = upper/lower segment ratio (use symphysis pubis as midpoint)
    - Newborn = 1.7, adult male = 0.9, adult female = 1.0

**Scoliosis Screening**

- Despite mass school screening implemented in parts of the USA and Canada in the 1970s-90s, the Canadian (1994) and American (2004) Task Forces on Preventive Health Care do NOT currently recommend routine screening using the Forward Bend Test (FBT). Cohort studies indicate that the Forward Bend Test has poor sensitivity for identifying pathological curves. Furthermore, there is no evidence to suggest that screening and increased bracing lead to better outcomes
Average Growth Parameters

Table 3. Parameter of Average Growth at Birth

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normal</th>
<th>Growth</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Birth Weight</td>
<td>3.25 kg (7 lbs)</td>
<td>Gain 20-30 g/d (term neonate)</td>
<td>Weight loss (up to 10% of birth weight) in first 7 d of life is normal. Neonate should regain birth weight by ~10-14 d of age.</td>
</tr>
<tr>
<td></td>
<td>2 x birth wt by 4-5 mo</td>
<td>3 x birth wt by 1 yr</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4 x birth wt by 2 yr</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Length/Height</td>
<td>50 cm (20 in)</td>
<td>25 cm in 1st yr</td>
<td>Measure supine length until 2 yr of age, then measure standing height</td>
</tr>
<tr>
<td></td>
<td>12 cm in 2nd yr</td>
<td>8 cm in 3rd yr then</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4-7 cm/yr until puberty</td>
<td>1/2 adult height at 2 yr</td>
<td></td>
</tr>
<tr>
<td>Head Circumference</td>
<td>35 cm (14 in)</td>
<td>2 cm/mo for 1st 3 mo</td>
<td>Measure around occipital, parietal, and frontal prominences to obtain the greatest circumference</td>
</tr>
<tr>
<td></td>
<td>1 cm/mo at 3-6 mo</td>
<td>0.5 cm/mo at 6-12 mo</td>
<td></td>
</tr>
</tbody>
</table>

Reflexes

Table 4. Reflexes

<table>
<thead>
<tr>
<th>Reflex</th>
<th>Maneuver to Elicit Reflex</th>
<th>Appropriate Reflex Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moro</td>
<td>Infant placed semi-upright, head supported by examiner’s hand, sudden withdrawal of supported head with immediate return of support</td>
<td>Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms</td>
</tr>
<tr>
<td>Galant</td>
<td>Infant held in ventral suspension and one side of back is stroked along paravertebral line</td>
<td>Pelvis will move in the direction of stimulated side</td>
</tr>
<tr>
<td>Grasp</td>
<td>Placement of examiner’s finger in infant’s palm</td>
<td>Flexion of infant’s fingers</td>
</tr>
<tr>
<td>ATNR</td>
<td>Turn infant’s head to one side</td>
<td>“Fencing” posture (extension of ipsilateral leg and arm and flexion of contralateral arm)</td>
</tr>
<tr>
<td>Placing</td>
<td>Dorsal surface of infant’s foot placed touching edge of table</td>
<td>Flexion followed by extension of ipsilateral limb up onto table (resembles primitive walking)</td>
</tr>
<tr>
<td>Rooting</td>
<td>Tactile stimulus near mouth</td>
<td>Infant pursues stimulus with face</td>
</tr>
<tr>
<td>Parachute</td>
<td>Tilt infant to side while in sitting position</td>
<td>Ipsilateral arm extension, present by 6-8 mo</td>
</tr>
</tbody>
</table>

ATNR = asymmetric tonic neck reflex

Abnormal Reflex Response

- Absence may suggest CNS abnormality
- Persistence after 4-6 mo may indicate abnormality (e.g. cerebral palsy)
- Asymmetry suggests focal motor lesions (e.g. brachial plexus injury)
- Upgoing plantar reflex (Babinski’s sign) normal in infants up to age 2 yr

Developmental Milestones

Table 5. Developmental Milestones

<table>
<thead>
<tr>
<th>Age*</th>
<th>Gross Motor</th>
<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 mo</td>
<td>Tums head side to side when supine</td>
<td>Hands fist, thumb in fist</td>
<td>Cries, startles to loud noises</td>
<td>Calms when comforted</td>
</tr>
<tr>
<td>2 mo</td>
<td>Briefly raises head when prone, holds head erect when upright</td>
<td>Pulls at clothes</td>
<td>Variety of sounds (e.g. coos, gurgles)</td>
<td>Smiles responsively, recognizes and calms down to familiar voice, follows movement with eyes</td>
</tr>
<tr>
<td>4 mo</td>
<td>Lifts head and chest when prone, holds head steady when supported sitting, rolls prone to supine</td>
<td>Briefly holds object when placed in hand, reaches for midline objects</td>
<td>Turns head towards sounds</td>
<td>Laughs responsively, follows moving toy or person with eyes, responds to people with excitement (e.g. leg movement)</td>
</tr>
<tr>
<td>6 mo</td>
<td>Tripod sit, pivots in prone position</td>
<td>Ulnar or raking grasp, transfers objects from hand to hand, brings objects to mouth</td>
<td>Babbles</td>
<td>Stranger anxiety, beginning of object permanence</td>
</tr>
<tr>
<td>9 mo</td>
<td>Sits well without support, crawls, pulls to stand, stands with support</td>
<td>Early pincer grasp with straight wrist</td>
<td>“Mama, dada” – appropriate, imitates 1 word, responds to “no” regardless of tone</td>
<td>Plays games (e.g. peek-a-boo), reaches to be picked up</td>
</tr>
<tr>
<td>12 mo</td>
<td>Gets into sitting position without help, stands without support, walks while holding on</td>
<td>Neat pincer grasp, releases ball with throw</td>
<td>2 words, follows 1-step command, uses facial expression, sounds, actions to make needs known</td>
<td>Responds to own name, separation anxiety begins</td>
</tr>
</tbody>
</table>

*Use corrected GA until 2 yr

Developmental Red Flags

- Gross motor: not walking at 18 mo
- Fine motor: handedness at <10 mo
- Speech: <3 words at 18 mo
- Social: not smiling at 3 mo; not pointing at 15-18 mo
- See the Nipissing District Developmental Screen for a checklist of important 18 mo milestones: www.ndds.ca
Table 5. Developmental Milestones (continued)

**Nutrition**

**Dietary Requirements**

<table>
<thead>
<tr>
<th>Weight</th>
<th>Needs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;10 kg</td>
<td>100 kcal/kg/d</td>
</tr>
<tr>
<td>10-20 kg</td>
<td>1,000 cal + 50 kcal/kg/d for each kg &gt;10</td>
</tr>
<tr>
<td>&gt;20 kg</td>
<td>1,500 cal + 20 kcal/kg/d for each kg &gt;20</td>
</tr>
</tbody>
</table>

**Dietary Recommendations**

- 0-6 mo: breast milk or formula
  - exclusive breast milk during first 6 mo recommended over formula unless contraindicated
  - breastfed infants require supplements: vitamin K (all babies get at birth, breastfed or not), vitamin D (400-800 IU/d), fluoride (after 6 mo if not sufficient in water), iron (6-12 mo, only if not receiving fortified cereals/meat/meat alternatives)
- >6 mo: solid food introduction – do not delay beyond 9 mo
  - 2-3 new foods per wk with a few days in between each food to allow time for adverse reaction identification
  - suggested order of introduction
    - meat, meat alternatives, and iron-enriched cereal (rice cereal is least allergenic)
    - pureed vegetables
    - fruit
- 9-12 mo: finger foods and switch to homogenized (3%) milk
  - feed child based on hunger/satiety cues; encourage self-feeding and introduce open cup
  - foods to avoid
    - honey until past 12 mo (risk of botulism)
    - added sugar, salt
    - excessive milk (i.e. no more than 16 oz/d after 1 yr)
    - juice (not nutritious, too much sugar)
    - anything that is a choking hazard (chunks, round foods like grapes)

**Breastfeeding**

- content of breast milk
  - colostrum (first few days): clear, rich in nutrients (i.e. high protein, low fat), immunoglobulin
  - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- advantages
  - easily digested, low renal solute load
  - immunologic
    - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits *E. coli* growth in intestine)
    - lower pH promotes growth of lactobacillus in GI tract
  - parent-child bonding
  - economical, convenient

---

**Peanut Allergies in Children**

*NEJM 2015;372(9):803-813*

**Study:** 840 children identified as “at risk to peanut allergy” due to severe eczema, egg allergy, or both were split into two cohorts depending on their pre-existing sensitivity to peanut extract on skin-prick test. These two cohorts were randomized to peanut consumption or avoidance up until 60 mo of age.

**Results:** In the cohort with negative skin-prick test at start of study, prevalence of peanut allergy at 60 mo of age was 13.7% in peanut avoidance and 1.9% in the peanut consumption group. In cohort with positive skin-prick test at start of study, prevalence of peanut allergy at 60 mo of age was 35.3% in peanut avoidance and 10.8% in peanut consumption group.

**Conclusion:** Early introduction of peanuts significantly decreased prevalence of peanut allergies in children deemed “at risk to peanut allergy”.

---

**Dietary Exposures and Allergy Prevention in High-Risk Infants**

*Pediatric Child Health 2013;18(10):545-549*

There is no evidence that restriction of highly allergenic foods is beneficial in the first year of life. Later introduction of peanut, fish, or egg does not prevent, and may increase the risk of developing food allergy. There is also no evidence that dietary restrictions during pregnancy or breastfeeding are protective to the child.
contraindicated if mother
  - is receiving chemotherapy or radioactive compounds
  - has HIV/AIDS, active untreated TB, herpes in breast region
  - is using >0.5 g/kg/d of alcohol or illicit drugs
  - is taking medications known to cross to breast milk
  - OCPs are not a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
  - MotherRisk™ Program – valuable research and counselling on reproductive risk or safety of drugs and chemicals

complications in infant
  - breastfeeding jaundice (first 1-2 wk): due to lack of maternal milk production and subsequent infant dehydration (see Jaundice, P70)
  - breast milk jaundice (0.5% of newborns, persists up to 4-6 mo): rare, not fully understood, thought to be due to substances in breast milk that inhibit conjugation of bilirubin or increase enterohepatic circulation of bilirubin, likely a biochemical problem; check bilirubin to rule out conjugated hyperbilirubinemia
  - baby presents healthy and thriving, and jaundice resolves
  - poor weight gain: consider dehydration or FIT
  - oral candidiasis (thrush): check baby’s mouth for white cheesy material that does not scrape off; treat baby with antifungal such as nystatin (Mycostatin®); can occur in breast or bottle-fed infants

Note: This list is not exhaustive. For more details, see Rourke Baby Record (http://www.rourkebabyprecord.ca/pdf/RBR2011Enr_Eng.pdf)
Common Complaints

Breath Holding Spells

- epidemiology: 0.1-5% of healthy children 6 mo-4 yr of age, usually start during first year of life
- etiology: child is provoked (usually by anger, injury, or fear) → holds breath and becomes silent → spontaneously resolves or loses consciousness
- types
  - cyanotic (more common), usually associated with anger/frustration
  - pallid, usually associated with pain/surprise
- management
  - usually resolves spontaneously and rarely progresses to seizure
  - help child control response to frustration and avoid drawing attention to spell

Circumcision

- elective procedure
  - not covered by OHIP in Ontario, but recent evidence shows health benefits outweigh risks and justify access to procedure
  - often for religious or culture reasons
- benefits: prevention of phimosis and slightly reduced incidence of UTI, STI, balanitis, cancer of the penis
- complications (<1%): local infection, bleeding, urethral injury
- contraindications: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

Crying/Fussing Child

- history
  - description of baseline feeding, sleeping, crying patterns
  - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
  - feeding intolerance: gastroesophageal reflux with esophagitis, N/V, diarrhea, constipation
  - trauma
  - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk
  - inconsistent history, pattern of numerous emergency department visits, high-risk social situations all raise concern of maltreatment

</tbody>
</table>
Infantile Colic

- definition: unexplained paroxysms of irritability and crying for >3 h/d, >3 d/wk for >3 wk in an otherwise healthy, well-fed baby (rule of 3s)
- epidemiology: 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- etiology: lag in development of normal peristaltic movement in gastrointestinal tract; other theories suggest a lack of self-soothing mechanisms or extreme of normal
- management
  - parental relief, rest, and reassurance
  - hold baby, soother, car ride, music, vacuum, check diaper
  - medications (Ovol® drops, gripe water) have no proven benefit, some evidence for probiotics
  - if breastfeeding, elimination of cow’s milk protein from mother’s diet (effective in very small percentage of cases)
  - try casein hydrolysate formula (Nutramigen®)
  - time – all resolve, most in the first 2-3 mo of life

Dentition and Caries

Dentition
- primary dentition (20 teeth)
  - first tooth at 5-9 mo (lower incisor), then 1/mo
  - 6-8 central teeth by 1 yr
  - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
  - first adult tooth is 1st molar at 6 yr, then lower incisors

Caries
- milk caries: decay of superior front teeth and back molars in first 4 yr of life
- cause: often due to prolonged feeding (e.g. put to bed with bottle, prolonged breastfeeding)
- prevention
  - no bottle at bedtime, clean teeth after last feed
  - minimize juice and sweetened pacifier
  - clean teeth with soft damp cloth or toothbrush and water
  - water fluoridation

Enuresis

Definition
- involuntary urinary incontinence by day and/or night in child >5 yr

General Approach
- should be evaluated if dysuria, change in colour, odour, stream, secondary or diurnal, change in gait, stool incontinence

Primary Nocturnal Enuresis
- definition: involuntary loss of urine at night, bladder control has never been attained
- epidemiology: boys > girls; 10% of 6 yr olds, 3% of 12 yr olds, 1% of 18 yr olds
- etiology: developmental disorder or maturational lag in bladder control while asleep
- management
  - time and reassurance (~20% resolve spontaneously each yr)
  - behaviour modification (limiting fluids, voiding prior to sleep), bladder retention exercises, scheduled toileting overnight has limited effectiveness
  - conditioning: “wet” alarm wakes child upon voiding (70% success rate)
  - medications (considered second line therapy, may be used for sleepovers/camp): DDAVP oral tablets (high relapse rate, costly), imipramine (Tofranil®) (rarely used, lethal if overdose, cholinergic side effects)

Secondary Enuresis
- definition: involuntary loss of urine at night, develops after child has sustained period of bladder control (>6 mo)
- etiology: inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord), focused on other activities, secondary to organic disease (UTI, DM, DI, neurogenic bladder, CP, seizures, pinworms)
- management: treat underlying cause

Antidiuretic Hormone Regulation in Primary Nocturnal Enuresis
Arch Dis Child 1995;73(6):508-11
Treatment of primary nocturnal enuresis using DDAVP is based upon the hypothesis that ADH secretion is insufficient at night. The known efficacy of the treatment on the one hand, and persisting doubts about its theoretical basis on the other, formed the background of the present study. Ten children (mean age 10.5 yr) with primary nocturnal enuresis were compared with a corresponding control group of eight patients. Diurnal and nocturnal urine production, ADH secretion, and plasma osmolality were determined. No differences between the two groups were found for urine production, ADH levels during day and night, or plasma osmolality. However, in order to regulate plasma osmolality the enuretic children required a markedly greater output of ADH 2.87 pg/millimol/kg compared with 0.56 in the controls (p < 0.01). The results are consistent with the established fact that ADH secretion is a function of plasma osmolality, and they contradict the hypothesis that urine production is increased at night in enuretics because of lower ADH secretion.
Diurnal Enuresis
• definition: daytime wetting (60-80% also wet at night)
• etiology: micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders, DM
• management: treat underlying cause, behavioural (scheduled toileting, double voiding, good bowel program), pharmacotherapy

Encopresis
• definition: fecal incontinence in a child >4 yr old, at least once per mo for 3 mo
• prevalence: 1-1.5% of school-aged children (rare in adolescence); M:F = 6:1 in school-aged children
• causes: chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, anorectal malformations, bowel obstruction

Retentive Encopresis
• definition: child holds bowel movement, develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
• etiology
  • physical: painful stooling often secondary to constipation
  • emotional: disturbed parent-child relationship, coercive toilet training, social stressors
• clinical presentation
  • history
    • crosses legs or stands on toes to resist urge to defecate
    • distressed by symptoms, soiling of clothes
    • toilet training coercive or lacking in motivation
    • may show oppositional behaviour
    • abdominal pain
  • physical exam
    • digital rectal exam: large fecal mass in rectal vault
    • anal fissures (result from passage of hard stools)
    • palpable stool in LLQ
• management
  • complete clean-out of bowel: PEG 3350 given orally is most effective, enemas and suppositories may be second line therapies, but these are invasive and often less effective
  • maintenance of regular bowel movements (see Pediatric Gastroenterology, Constipation Treatment, P38)
  • assessment and guidance regarding psychosocial stressors
  • behavioural modification
• complications: recurrence, toxic megacolon (requires >3-12 mo to treat), bowel perforation

Toilet Training
• 90% of children attain bladder control before bowel control
• generally, females train earlier than males
• 25% by 2 yr (in North America), 98% by 3 yr have daytime bladder control
• signs of toilet readiness
  • ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several hours (large enough bladder), can recognize need to go, able to remove clothing

Failure to Thrive
• definition
  • weight <3rd percentile, falls across two major percentile curves, or <80% of expected weight for height and age
  • inadequate caloric intake most common factor in poor weight gain
  • may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
  • factors affecting physical growth: genetics, intrauterine factors, internal time clock, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
• clinical presentation
  • history
    • nutritional intake
    • current symptoms
    • past illnesses

**Energy Requirements**
- 0-10 kg: 100 kcal/kg/d
- 10-20 kg: 1,000 kcal + 50 kcal/kg/d for each kg >10
- >20 kg: 1,500 kcal + 20 kcal/kg/d for each kg >20
• family history: growth, puberty, parental height and weight including mid-parental height
• psychosocial history
• physical exam
• growth parameters, plotted: height, weight, head circumference, arm span
• vital signs
• complete head to toe exam
• dysmorphic features or evidence of chronic disease
• upper to lower segment ratio
• sexual maturity staging
• signs of maltreatment or neglect
• investigations (as indicated by clinical presentation)
  • CBC, blood smear, electrolytes, T4, TSH
• bone age x-ray
• chromosomes/karyotype
• chronic illness: chest (CXR, sweat Cl\(^-\)), cardiac (CXR, ECG, Echo), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)

</tbody>
</table>

BA = bone age; CA = chronological age; HC = head circumference; Ht = height; Wt = weight

Non-Organic FTT (90%)
• most common cause of FTT
• results from complex factors in parent-child relationship
  • dietary intake, knowledge about feeding, improper mixing of formula, economic factors
  • feeding environment
  • parent-child interaction, attachment
  • child behaviours, hunger/satiety cues
  • social factors: stress, poverty
• management
  • most as outpatient using multidisciplinary approach: primary care physician, dietitian, psychologist, social work, CAS
  • medical: oromotor problems, iron-deficiency anemia, gastroesophageal reflux
  • nutritional: educate about age-appropriate foods, calorie boosting, mealtime schedules and environment; goal to reach 90-110% IBW, correct nutritional deficiencies, and promote catch-up growth/development
  • behavioural: positive reinforcement, mealtime environment

Organic FTT (10%)
• inadequate intake: non-organic, vomiting, oromotor dysfunction, anorexia
• excessive consumption: CHD, CF, hyperthyroidism
• abnormal utilization: inborn errors of metabolism
• excessive output: IBD, celiac, malabsorption
• management: treat specific cause

Energy Requirements
• see Nutrition, P6

Obesity
• definition: BMI >95th percentile for age and height
• risk factors: genetic predisposition (e.g. both parents obese – 80% chance of obese child)
• etiology: organic causes are rare (<5%), but may include Prader-Willi, Carpenter, Turner, Cushing syndromes, hypothyroidism
• complications: association with HTN, dyslipidemia, slipped capital femoral epiphysis, type 2 DM, asthma, obstructive sleep apnea, gynecostasia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. bullying, decreased self-esteem, unhealthy coping mechanisms, depression)
• childhood obesity often persists into adulthood
• management
  • encouragement and reassurance; engagement of entire family
  • diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults and very low calorie diets are not encouraged
- behaviour modification: increase activity, change eating habits/meal patterns
- education: multidisciplinary approach, dietitian, counselling
- surgery and pharmacotherapy are rarely used in children
- increase physical activity (30 min/day), reduce screen time

**Poison Prevention**

- keep all types of medicines, vitamins, and chemicals locked up in a secure container
- potentially dangerous: medications, illicit drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- always read labels before administering medicine to ensure correct medication drug and dose and/or speak with a pharmacist or healthcare provider

**Pediatric Exanthems** (see Infectious Pediatric Exanthems, P56)

**Drug Reactions** (see Dermatology, D22)

**Acne** (see Dermatology, D11)
Sleep Disturbances

Types of Sleep Disturbances

• insufficient sleep quantity
  ▪ difficulty falling asleep (e.g. limit setting sleep disorder)
  ▪ preschool and older children
  ▪ bedtime resistance
  ▪ due to caregiver’s inability to set consistent bedtime rules and routines
  ▪ often exacerbated by child’s oppositional behaviours

• poor sleep quality
  ▪ frequent arousals (e.g. sleep-onset association disorder)
  ▪ infants and toddlers
  ▪ child learns to fall asleep only under certain conditions or associations (e.g. with parent, held, rocked or fed, with light on, in front of television), and loses ability to self-soothe
  ▪ during the normal brief arousal periods of sleep (q90-120 min), child cannot fall back asleep because same conditions are not present

• obstructive sleep apnea
  ▪ epidemiology: 1-5% of preschool aged children, more common in African American children
  ▪ definition: partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
  ▪ features: snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
  ▪ sequelae: cardiovascular (HTN/LV remodeling due to sympathetic activation), growth, cognitive, and behavioural deficits
  ▪ risk factors: adenotonsillar hypertrophy, obesity
  ▪ management: watchful waiting, weight reduction, airway pressure devices, or surgery depending on the cause
  ▪ adenotonsillectomy does not improve executive function or attention but reduces symptoms and improves behaviour, quality of life, and polysomnographic findings

• parasomnias
  ▪ episodic nocturnal behaviours (e.g. sleepwalking, sleep terrors, nightmares)
  ▪ often involves cognitive disorientation and autonomic/skeletal muscle disturbance

Management of Sleep Disturbances

• set strict bedtimes and “wind-down” routines
• do not send child to bed hungry
• positive reinforcement for: limit setting sleep disorder
• always sleep in own bed, in a dark, quiet, and comfortable room
• do not use bedroom for timeouts
• systematic ignoring and gradual extinction for: sleep-onset association disorder

Nightmares

• epidemiology: common in boys, 4-7 yr old
• associated with REM sleep (anytime during night)
• features: upon awakening, child is alert and clearly recalls frightening dream ± associated with daytime stress/anxiety
• management: reassurance

Night Terrors

• epidemiology: 15% of children have occasional episodes
• abrupt sitting up, eyes open, screaming
• clinical features: occurs in early hours of sleep, stage 4 of sleep; signs of panic and autonomic arousal, no memory of event, inconsolable, stress/anxiety can aggravate them
• course: remits spontaneously at puberty
• management: reassurance for parents, ensure child is safe (e.g. if sleepwalks)

Sudden Infant Death Syndrome

Definition

• sudden and unexpected death of an infant <12 mo of age in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology

• 0.5/1,000 (leading cause of death between 1-12 mo of age); M:F = 3:2
• more common in children placed in prone position
• in full term infants, peak incidence is 2-4 mo, 95% of cases occur by 6 mo
• increase in deaths during peak RSV season
• most deaths occur between midnight and 8 AM
Risk Factors
- prematurity, smoking in household, socially disadvantaged, higher incidence in Aboriginals and African Americans
- risk of SIDS is increased 3-5x in siblings of infants who have died of SIDS
- bedsharing: sleeping on a sofa, sleeping with an infant after consumption of alcohol/street drugs or extreme fatigue, infant sleeping with someone other than primary caregiver

Prevention
- “Back to Sleep, Front to Play” (place infant on back when sleeping)
- allow supervised play time daily in prone position (“tummy time”)
- alarms, monitors not recommended – increase anxiety, do not prevent life-threatening events
- avoid overheating and overdressing
- appropriate infant bedding (firm mattress; avoid loose bedding, pillows, stuffed animals, and crib bumper pads)
- no smoking
- pacifiers appear to have a protective effect; do not reinsert if falls out during sleep

Child Abuse and Neglect

Definition
- an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that harms a child

Legal Duty to Report
- upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the CAS to personally disclose all information relevant to the child safety concern
- duty to report overrides patient confidentiality; physician is protected against liability

Ongoing Duty to Report
- if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CAS must be made

Risk Factors
- environmental factors: social isolation, poverty, domestic violence
- caregiver factors: personal history of abuse, psychiatric illness, substance abuse, single parent family, poor social and vocational skills, below average intelligence
- child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

Physical Abuse

History
- history that is not compatible with physical findings, or history not reproducible
- delay in seeking medical attention that is unexplained by other factors

Physical Exam
- physical findings not explained by underlying medical condition
- growth parameters (weight, height, head circumference)
- recurrent or multiple injuries not explained by accidental injury or child’s development level
- patterned skin injuries: belt buckle, hand prints, burns that do not match provided history
- injury location: bruises on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek; bruises on ears; posterior rib/metaphyseal/scapular/vertebral/ternal fractures (more suspicious for non-accidental injuries); immersion burns (e.g. hot water)
- altered mental status: head injury, poisoning
- head trauma is the leading cause of death in child maltreatment (e.g. acceleration-deceleration forces [shaking], direct force application [blow or impact])

Investigations
- document all injuries on a body diagram: type, location, size, shape, colour, pattern
- photography of skin injuries is ideal (police or hospital photography preferred; do not use physician’s personal camera)
- rule out medical causes of bruising/fracture with appropriate investigations:
  - if fractures evident: Ca\(^{2+}\), Mg\(^{2+}\), PO\(_4\)^{3-}, ALP, PTH, Vitamin D, renal function, and bone density
  - if bruising present: CBC, INR, PTT, von Willebrand factor, factors VII/IX/X/XIII
  - screen for abdominal trauma (transaminases and amylase): if increased, abdo CT recommended
  - skeletal survey in children <2 yr
    - bone scan can be beneficial for assessing rib fractures (not helpful for skull or metaphyseal region due to active bone growth) – consider bone scan if equivocal findings on initial skeletal survey
    - dilated eye examination by pediatric ophthalmologist to rule out retinal hemorrhage
    - be aware of “red herrings” (e.g. Mongolian blue spots vs. bruises)
  - neuroimaging: CT and/or MRI

Apparent Life-Threatening Events
A group of conditions often marked by an episode of apnea, cyanosis, change in tone, or change in mental status occurring in a child, where an observer fears the child may be dying. There is no clear connection between most ALTEs and SIDS. Evaluating for a cause of the ALTE (e.g. infection, cardiac, neurologic) is guided by history, physical exam, and period of observation
Sexual Abuse

**Epidemiology**
- peak ages at 2-6 yr and 12-16 yr
- most perpetrators are male and known to child
  - in decreasing order: family member, non-relative known to victim, stranger

**History**
- diagnosis usually depends on child disclosing to someone or forensic interview done by a trained individual
- psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of trust, low self-esteem, school failure, sexually aggressive behaviour, advanced sexual knowledge, sexual preoccupation or play

**Physical Exam**
- recurrent UTIs, pregnancy, STIs, vaginitis, vaginal bleeding, pain, genital injury, enuresis

**Investigations**
- depend on presentation, age, sex, and pubertal development of child
  - sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
  - rule out STI, UTI, pregnancy (consider STI prophylaxis or emergency contraception)
  - rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)

Neglect

**History**
- from child and each caregiver separately (if possible)

**Physical Exam**
- head to toe (do not force), growth parameters, nutrition status
- dental care
- emotional state

**Investigations**
- blood tests to rule out medical conditions (e.g. thrombocytopenia or coagulopathy)

Management of Physical Abuse, Child Abuse, and Neglect
- report all suspicions to CAS; request emergency visit if imminent risk to child or any siblings in the home
- acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
- arrange consultation to social work and appropriate follow-up
- may need to discharge child directly to CAS or to responsible guardian under CAS supervision

Adolescent Medicine

Adolescent History (HEEADSSS)
- tailor your history according to the clinical context

**Home:** Who do you live with? What kind of place do you live in?

**Education/Employment:** What grade are you in? What are your favourite subjects? What was your average on your last report card?

**Eating:** Tell me about your meals/snacks in a typical day. Have you ever gone on a diet? (see Eating Disorders, Psychiatry, PS32)

**Activities:** What do you do after school? On the weekends? How much time do you spend on the computer/watching TV every day? Do you use social media (i.e. Facebook, Twitter, Instagram, etc.)?

**Drugs:** Which seems to be more popular at your school, alcohol or drugs? How often do you drink/smoke marijuana/take other drugs? Do you smoke cigarettes? When you drink, do you usually get drunk? Have you ever passed out or not been able to remember what happened while you were drinking? Has anything bad ever happened to you while you were drunk or stoned? (see Substance Abuse, Psychiatry, PS23)

**Sexuality:** Are you romantically interested in anyone? When you think about having sex with someone, do you think about girls, boys, or both? Have you ever had sex with anyone? Whether the answer is yes or no, the next question is: What activities would you include in the term ‘having sex’? What do you do to prevent getting a STI/getting pregnant/getting someone pregnant? Has anyone ever given you money, drugs, or other stuff in exchange for sex? (see Sexually Transmitted Infections, Gynecology, GY25)

Presentation of Neglect
- FTT, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents, no stranger anxiety

Rates of drug use in high school students who have used in the past year: alcohol (58.2%), cannabis (25.6%), tobacco (11.7%)

Date rape comprises 80% of sexual assault in teenagers
Suicidality/Depression: On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Is there a difference between school days and the weekend? Have you ever thought seriously about suicide? Did you make a plan? (see Depression/Suicide, Psychiatry PS9, PS4)

Safety/Violence: Do you ever get into a car with a driver who has been drinking? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

See Normal and Abnormal Pubertal Development, P31

Cardiology

Congenital Heart Disease

Prenatal Circulation

Embryologic Development
- most critical period of fetal heart development is between 3-8 wk gestation
- single heart tube grows rapidly, forcing it to bend back upon itself and assume the shape of a four chambered heart; insults at this time are most likely to lead to CHD

Before Birth
- fetal lungs are bypassed by flow through fetal shunts
  - ductus arteriosus: connection between pulmonary artery and aorta
  - foramen ovale: connection between right and left atria
  - ductus venosus: connection between umbilical vein and inferior vena cava

At Birth
- with first breath, lungs open up → pulmonary resistance decreases → pulmonic blood flow increases
- separation of low resistance placenta → systemic circulation becomes a high resistance system → ductus venosus closure
- increased pulmonic flow → increased left atrial pressures → foramen ovale closure
- increased oxygen concentration in blood after first breath → decreased prostaglandins → ductus arteriosus closure
- closure of fetal shunts and changes in vascular resistance → infant circulation assumes normal adult flow

Prevalence of depression: 1-2% in pre-pubertal children and 6-8% in adolescents
Epidemiology
• 8/1,000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; VSD is the most common lesion

Investigations
• Echo, ECG, CXR
• pre and postductal oxygen saturations, 4 limb BPs, hyperoxia test

CYANOTIC VS. ACYANOTIC CONGENITAL HEART DISEASE
• cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 30 g/dL.
• acyanotic heart disease (i.e. L to R shunt, obstruction occurring beyond lungs): blood passes through pulmonic circulation → oxygenation takes place → low levels of deoxygenated blood in systemic circulation → no cyanosis
• cyanotic heart disease (i.e. R to L shunt): blood bypasses the lungs → no oxygenation occurs → high levels of deoxygenated hemoglobin enters the systemic circulation → cyanosis

Figure 2. Common congenital heart diseases

Acyanotic Congenital Heart Disease

1. LEFT-TO-RIGHT SHUNT LESIONS
• extra blood is displaced through a communication from the left to the right side of the heart → increased pulmonary blood flow → increased pulmonary pressures
• shunt volume is dependent upon three factors: (1) size of defect, (2) pressure gradient between chambers or vessels, and (3) peripheral outflow resistance
• untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular HTN and RVH, and ultimately R to L shunts

Atrial Septal Defect
• 3 types: ostium primum (common in DS), ostium secundum (most common type, 50-70%), sinus venosus (defect located at entry of superior vena cava into right atrium)
• epidemiology: 6-8% of congenital heart lesions
• natural history
  ▪ 80-100% spontaneous closure rate if ASD diameter <8 mm
  ▪ if remains patent, CHF and pulmonary HTN can develop in adult life
• clinical presentation
  ▪ history: often asymptomatic in childhood
  ▪ physical exam: grade 2-3/6 pulmonic outflow murmur, widely split and fixed S2
  ▪ children with large ASDs may have signs of heart failure (tachypnea, FTT, hepatomegaly, pulmonary rales/retractions)
• investigations
  ▪ ECG: RAD, mild RVH, RBBB
  ▪ CXR: increased pulmonary vasculature, cardiac enlargement
  ▪ Echo: test of choice
• management: elective surgical or catheter closure between 2-5 yr of age

Ventricular Septal Defect
• most common congenital heart defect (30-50%)
• small VSD (majority)
  ▪ clinical presentation
    ▪ history: asymptomatic, normal growth and development
    ▪ physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
investigations: ECG and CXR are normal; Echo to confirm diagnosis
management: most close spontaneously

- moderate-to-large VSD
  epidemiology: CHF by 2 mo; late secondary pulmonary HTN if left untreated
  clinical presentation
    - history: delayed growth, decreased exercise tolerance, recurrent URTIs or “asthma” episodes
    - physical exam: holosystolic murmur at LLSB, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur
  investigations
    - ECG: LVH, LAH, RVH
    - CXR: increased pulmonary vasculature, cardiomegaly, CHF
    - Echo: diagnostic
  management: treatment of CHF and surgical closure by 1 yr old

Patent Ductus Arteriosus
- patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)
- epidemiology
  - 5-10% of all congenital heart defects
  - delayed closure of ductus is common in premature infants (1/3 of infants <1,750 g); this is different from PDA in term infants
  - natural history: spontaneous closure common in premature infants, less common in term infants
- clinical presentation
  - history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
  - physical exam: tachycardia, bounding pulses, hyperactive precordium, wide pulse pressure, continuous “machinery” murmur best heard at left infraclavicular area
- investigations
  - ECG: may show left atrial enlargement, LVH, RVH
  - CXR: normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery
  - Echo: diagnostic
- management
  - indomethacin (Indocid®): antagonizes prostaglandin E2, which maintains ductus arteriosus patency; only effective in premature infants
  - catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd mo of life

2. OBSTRUCTIVE LESIONS
- present with decreased urine output, pallor, cool extremities and poor pulses, shock, or sudden collapse

Coarctation of the Aorta
- definition: narrowing of aorta (almost always at the level of the ductus arteriosus)
- epidemiology: commonly associated with bicuspid aortic valve (50%); Turner syndrome (35%)
- clinical presentation
  - history: often asymptomatic
  - physical exam
    - blood pressure discrepancy between upper and lower extremities (increased suspicion/severity if >20 mmHg difference)
    - diminished or delayed femoral pulses relative to brachial (i.e. brachial-femoral delay)
    - possible systolic murmur with late peak at apex, left axilla, and left back
    - if severe, presents with shock in the neonatal period when the ductus arteriosis closes
- investigations: ECG shows RVH early in infancy, LVH later in childhood; Echo or MRI for diagnosis
- prognosis: can be complicated by HTN; if associated with other lesions (e.g. PDA, VSD) can lead to CHF
- management: give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates; for older infants and children balloon arterioplasty may be an alternative to surgical correction

Aortic Stenosis
- 4 types: valvular (75%), subvalvular (20%), supravalvular, and idiopathic hypertrophic subaortic stenosis (5%)
- clinical presentation
  - history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope, or sudden death
  - physical exam: SEM at RUSB with aortic ejection click at the apex (only for valvular stenosis)
- investigations: Echo for diagnosis
- management: valvular stenosis is usually treated with balloon valvuloplasty, patients with subvalvular or supravalvular stenosis require surgical repair, exercise restriction required

Moderate-to-Large VSD
- Size of VSD is inversely related to intensity of murmur

Physical Exam for PDA
- (in term infant)
  - Heavy “machinery” murmur
  - Wide pulse pressure
  - Hyperactive precordium
  - Big bounding pulse

Figure 3. Patent ductus arteriosus

Figure 4. Coarctation of the aorta

Figure 4. Coarctation of the aorta
Pulmonary Stenosis
- 3 types: valvular (90%), subvalvular, or supravalvular
- definition of critical pulmonary stenosis: inadequate pulmonary blood flow, dependent on ductus for oxygenation, progressive hypoxia and cyanosis
- natural history: may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)
- clinical presentation
  - history: spectrum from asymptomatic to CHF
  - physical exam: wide split S2 on expiration, SEM at LUSB, pulmonary ejection click (for valvular lesions)
- investigations
  - ECG: RVH
  - CXR: post-stenotic dilation of the main pulmonary artery
  - Echo: diagnostic
- management: surgical repair if critically ill or if symptomatic in older infants/children

Cyanotic Congenital Heart Disease
- systemic venous return re-enters systemic circulation directly
- most prominent feature is cyanosis (O₂ sat <75%)
- hyperoxic test differentiates between cardiac and other causes of cyanosis
  - obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O₂
  - if PaO₂ improves to greater than 150 mmHg, cyanosis less likely cardiac in origin
- pre-ductal and post-ductal pulse oximetry
  - >5% difference suggests R to L shunt

1. RIGHT-TO-LEFT SHUNT LESIONS

Tetralogy of Fallot
- epidemiology: 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo of age
- pathophysiology
  - embryological defect due to anterior and superior deviation of the outlet septum leading to: VSD, RVOTO (i.e. pulmonary stenosis), over-riding aorta, and RVH
  - infants may initially have a L → R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R → L shunting with hypoxemia and cyanosis
  - degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- clinical presentation
  - history: hypoxic “tet” spells
    - during exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
    - clinical features include paroxysms of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO)
  - if severe, can lead to decreased level of consciousness, seizures, death
  - physical exam
    - single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), SEM at LSB
- investigations
  - ECG: RAD, RVH
  - CXR: boot-shaped heart, decreased pulmonary vasculature, right aortic arch (in 20%)
  - Echo: diagnostic
- management of spells: O₂, knee-chest position, fluid bolus, morphine sulfate, propranolol
- treatment: surgical repair at 4-6 mo of age; earlier if marked cyanosis or “tet” spells

2. OTHER CYANOTIC CONGENITAL HEART DISEASES

Transposition of the Great Arteries (TGA)
- epidemiology: 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonates
- pathophysiology: parallel pulmonary and systemic circulations
  - systemic: body → RA → RV → aorta → body
  - pulmonary: lungs → LA → LV → pulmonary artery → lungs
  - survival is dependent on mixing through PDA, ASD, or VSD
- physical exam
  - neonates: ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
  - VSD present: cyanosis is not prominent; CHF within first weeks of life
  - VSD absent: no murmur

Figures: Tetralogy of Fallot, Transposition of the great arteries
• investigations
  ᵉ ECG: RAD, RVH, or may be normal
  ᵉ CXR: egg-shaped heart with narrow mediastinum (“egg on a string”)
  ᵉ Echo: diagnostic

• management
  ᵉ symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
  ᵉ surgical repair: arterial switch performed in the first two weeks in those without a VSD while LV muscle is still strong

Total Anomalous Pulmonary Venous Return
• epidemiology: 1-2% of CHD
• pathophysiology
  ᵇ all pulmonary veins drain into right-sided circulation (systemic veins, RA)
  ᵇ no direct oxygenated pulmonary venous return to left atrium
  ᵇ often associated with obstruction at connection sites
  ᵇ ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
• management: surgical repair in all cases and required urgently for severe cyanosis

Truncus Arteriosus
• pathophysiology
  ᵇ single great vessel gives rise to the aorta, pulmonary, and coronary arteries
  ᵇ truncal valve overlies a large VSD
  ᵇ potential for coronary ischemia with fall in pulmonary vascular resistance
• management: surgical repair within first 6 wk of life

Hypoplastic Left Heart Syndrome
• epidemiology: 1-3% of CHD; most common cause of death from CHD in first month of life
• pathophysiology
  ᵇ LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coarctation of the aorta with resultant systemic hypoperfusion
  ᵇ systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
• management
  ᵇ intubate and correct metabolic acidosis
  ᵇ IV infusion of prostaglandin E1 to keep ductus open
  ᵇ surgical palliation (overall survival 50% to late childhood) or heart transplant

Congestive Heart Failure
• see Cardiology and Cardiac Surgery, C36

Etiology
• CHD
• cardiomyopathy (primary or secondary)
• high output circulatory states (e.g. anemia, AVMs, cor pulmonale, hyperthyroidism)
• non-cardiac (e.g. sepsis, renal failure)
• pressure overload (e.g. aortic stenosis/co-arctation, pulmonary stenosis, HTN)
• volume overload (e.g. L to R shunt, valve insufficiency)

History
• infant: feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
• child: decreased exercise tolerance, fatigue, decreased appetite, respiratory distress, frequent URTIs or “asthma” episodes
• orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children

Physical Findings
• 4 key features: tachycardia, tachypnea, cardiomegaly, hepatomegaly
• FTT
• alterations in peripheral pulses, four limb blood pressures (in some CHDs)
• dysmorphic features associated with congenital syndromes

Investigations
• CXR: cardiomegaly, pulmonary venous congestion
• ECG: sinus tachycardia, signs of underlying cause (heart block, atrial enlargement, hypertrophy, ischemia/infarct)
• Echo: structural and functional assessment
• blood work: CBC, electrolytes, BUN, Cr, LFTs
Management
• general: sitting up, O₂, sodium and water restriction, increased caloric intake
• pharmacologic: diuretics, afterload reduction (e.g. ACE inhibitor), β-blockers; digoxin rarely used
• curative: correction of underlying cause

Dysrhythmias

• see Cardiology and Cardiac Surgery, C17
• can be transient or permanent, congenital (structurally normal or abnormal), or acquired (toxin, infection, infarction)

Sinus Arrhythmia
• phasic variations with respiration (present in almost all normal children)

Sinus Tachycardia
• rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
• characterized by: beat-to-beat heart rate variability with changes in activity, P waves present/normal, PR constant, QRS narrow
• etiology: HTN, fever, anxiety, sepsis, anemia/hypoxia, PE, drugs, etc.
• differentiate from SVT (see below) by slowing the sinus rate (vagal massage, β-blockers) to identify sinus P waves

Premature Atrial Contractions
• may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitals toxicity

Premature Ventricular Contractions
• common in adolescents
• benign if single, uniform, disappear with exercise, and no associated structural lesions
• if not benign, may degenerate into more severe dysrhythmias

Supraventricular Tachycardia
• abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
• no beat-to-beat HR variability, >220 bpm (infants) or >180 bpm (children), P waves absent/normal, PR indeterminable, QRS usually narrow
• pre-excitation syndromes (subset of SVT): WPW syndrome, congenital defect (see Cardiology and Cardiac Surgery C23)

Complete Heart Block
• congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
• often diagnosed in utero (may lead to development of fetal hydrops)
• clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
• symptomatic patients need a pacemaker

Heart Murmurs

• 50-80% of children have audible heart murmurs at some point in their childhood
• most childhood murmurs are functional (e.g. "innocent") without associated structural abnormalities and have normal ECG and radiologic findings
• in general, murmurs can become audible or accentuated in high output states (e.g. fever, anemia)

Infective Endocarditis

- see Infectious Diseases, ID16

Development

Approach to Global Developmental Delay

- also known as Early Developmental Impairment

Definition

- performance significantly below average in two or more domains of development (gross motor, fine motor, speech/language, cognitive, social/personal, activities of daily living) in a child <5 yr of age
- predict a diagnosis of intellectual disability in the future

Epidemiology

- 5-10% of children have neurodevelopmental delay
- careful evaluation can reveal a cause in 50-70% of cases

Etiology

- CNS abnormalities (meningitis/encephalitis, brain malformation, trauma, etc.)
- sensory deficits (hearing, vision)
- environmental (psychosocial neglect, lead exposure, antenatal drug or alcohol exposure, etc.)
- genetic/chromosomal disorders (DS, Fragile X, etc.)
- metabolic disorders (inborn errors of metabolism, hypothyroidism, iron deficiency, etc.)
- obstetrical (prematurity, HIE, TORCH infections, etc.)
- sleep disorders
- seizures

Clinical Presentation

- history
  - intrauterine exposures, perinatal events
  - detailed developmental milestones: rate of acquisition, regression of skills
  - associated problems: feeding, seizures, behaviour, sleep
  - family history, consanguinity
  - social history
- physical exam
  - dysmorphic features, hepatosplenomegaly, neurocutaneous markers, growth parameters, detailed neurological examination
- investigations (guided by history and physical examination)
  - neurodevelopmental assessment, neuroimaging, vision and hearing test, EEG, sleep study
  - OT, PT, and/or SLP assessments
  - psychosocial evaluation
  - blood work (lead, CBC, ferritin, TSH)
  - genetics consultation (microarray, Fragile X testing, testing for inborn errors of metabolism)
Management
- dependent on specific area of delay
- therapy services (e.g. speech and language therapy for language delay, OT and/or PT for motor delay), early intervention services (e.g. infant development services, Ontario Early Years Centres)

Defining Intellectual Disability
- state of functioning that begins in childhood and is characterized by limitations in both intelligence and adaptive skills
- historically defined as an IQ <70
- often preceded by diagnosis of global developmental delay

Epidemiology
- 1% of general population; M:F = 1.5:1

Etiology
- any disorder that interferes with brain development and functioning
- prenatal (majority): TORCH infections, FASD
- genetic/metabolic: DS, Fragile X, PKU, untreated or delayed diagnosis of congenital hypothyroidism, CNS abnormalities, other chromosomal/metabolic disorders

Risk Factors
- male, consanguineous parents, family history, older maternal age, decreasing maternal education, certain ethnicities
- prenatal: pre-eclampsia, maternal malnutrition or DM
- perinatal: prematurity, low birth weight, birth trauma/hypoxia
- postnatal: ICH, CNS or other serious infection, hypoxia, environmental toxins, psychosocial deprivation, malnutrition

Clinical Presentation
- history
  - well below average general intellectual functioning
  - significant deficits in adaptive functioning in at least 2 of: communication, self-care, home-living, social skills, self-direction, academic skills, work, leisure, health, safety
- physical exam
  - check growth, dysmorphic features, complete physical exam
- investigations
  - standardized psychology assessment (includes IQ test and measure of adaptive functioning)
  - vision, hearing, and neurologic assessment
  - genetic and metabolic testing as indicated

Management
- main objective: enhance adaptive functioning level
- requires an interprofessional team with strong case coordination
- emphasize community-based treatment and early intervention
- individual/family therapy, behaviour management services, therapy services (e.g. OT, SLP), medications for associated conditions
- education: life skills, vocational training, communication skills, family education
- psychosocial support for individual and family; respite care

Prognosis
- higher rates of sensory deficits, motor impairment, behavioural/emotional disorders, seizures, psychiatric illness

Language Delay

Definition
- no universally accepted definition, but often identified around 18 mo of age with enhanced well baby visit
- if formally tested, performance on a standardized assessment of language is at least one standard deviation below mean of age
- can be expressive (ability to produce or use language), receptive (ability to understand language), or both

Epidemiology
- ~10-15% of 2 yr old children have a language delay, but only 4-5% remain delayed after 3 yr of age
- ~6-8% of school-aged children have specific language impairment (many of whom were not identified before school entry)
Etiology

- cognitive disability
- constitutional language delay
- genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
- hearing impairment
- mechanical problems: cleft palate, cranial nerve palsy
- medical condition: seizure disorder (includes acquired epileptic aphasia), CP, TORCH infection, iron deficiency, lead poisoning, etc.
- autism spectrum disorder
- psychosocial: neglect or abuse
- selective mutism

Risk Factors

- male, positive family history, prematurity, psychosocial (poverty, low parental education, maternal depression)

Clinical Presentation

- history
  - concerns about hearing, delay in language development or regression in previously normal language development
  - must determine if language delay is expressive, receptive, or mixed
  - children with expressive language delays may have concurrent behaviour problems or drooling (because of abnormal oral musculature)
- physical exam
  - guided by history: look for abnormal growth, dysmorphisms, unusual social interactions (lack of eye contact, not pointing)
  - include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate), and neurologic system (including tone)
- investigations
  - use of language specific screens in primary care setting: The Early Language Milestone, CAT/CLAMS, MCHAT, etc.
  - all children with suspected language delay MUST be referred to an audiologist for a hearing assessment
  - CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

Management

- specific to etiology
- often multidisciplinary and requires appropriate referrals: early intervention services, special education services, SLP, OHNS and dental professionals, general support services
- primary care provider can help reinforce family’s understanding of delay and provide follow-up and care coordination
- prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate daily activities, etc.

Prognosis

- depends on etiology
- if language delay persists beyond 5 yr old, more likely to have difficulties in adulthood
- persistent language delay is associated with poor academic performance, behavioural problems, social isolation

Learning Disabilities (Specific Learning Disorder DSM5)

Definition

- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child’s intellectual ability and their academic performance
- types: reading (dyslexia), writing, mathematics (dyscalculia)

Epidemiology

- prevalence: 10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder, major depressive disorder, oppositional defiant disorder, ADHD

Etiology

- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
  - genetic/metabolic: Turner syndrome, Klinefelter syndrome
  - perinatal: prematurity, low birth weight, birth trauma/hypoxia
postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition

- poor visual acuity is NOT a cause

**Risk Factors**
- positive family history, prematurity, other developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury

**Clinical Presentation**
- history and physical exam
  - school difficulties (academic achievement, behaviour, attention, social interaction)
  - development of negative self-concept → reluctance to participate even in areas of strength
  - social issues: overt hostility towards parents/teachers; difficulties making friends for several reasons (problems remembering names, difficulties with language to engage in conversations, inability to understand games and complex rules, etc.), bullying, and anxiety
  - look for dysmorphisms, complete physical exam
- investigations
  - standardized tests for IQ
  - individual scores on achievement tests in reading, mathematics, or written expression (WISC III, WRAT) >2 SD below that expected for age, education, and IQ

**Management**
- provide quality instruction for specific learning disability
- support student by modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
- consider grade retention in certain students (no guidelines exist, very rare in Ontario)
- specialized education placements that can provide educational remediation

**Prognosis**
- limited information available about persistence of learning disabilities over time
- low self-esteem, poor social skills, 40% school drop-out rate

---

**Fetal Alcohol Spectrum Disorder**

**Definition**
- term describing the range of effects of prenatal exposure to alcohol, including physical, mental, behavioural, and learning disabilities
- no “safe” level of alcohol consumption during pregnancy has been established
- spectrum includes: FAS, partial FAS, ARBD, and ARND

**Epidemiology**
- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

**Pathogenesis**
- specific mechanism of FASD is unknown, but hypotheses include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmission

**Diagnosis**
- often misdiagnosed or missed entirely
- diagnosis of FAS, ARBD, and ARND all require evidence of maternal drinking during pregnancy
- criteria for diagnosis of FAS
  - growth deficiency: low birth weight and/or decelerating weight over time not due to nutrition
  - characteristic pattern of facial anomalies: short palpebral fissures, flattened philtrum, thin upper lip, flat midface
  - CNS dysfunction: microcephaly and/or neurobehavioural dysfunction (hyperactivity, fine motor problems, attention deficits, learning disabilities, cognitive disabilities, difficulties in adaptive functioning, etc.)
- criteria for diagnosis of ARBD
  - congenital anomalies, including malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
  - CNS dysfunction (similar to FAS)
  - complex pattern of behavioural or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone
Management
- early diagnosis is essential to prevent secondary disabilities
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcome

Prognosis
- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behaviour, disrupted school experience, peer problems

Attention Deficit Hyperactivity Disorder
- see Psychiatry, Neurodevelopmental Disorders, PS40

Autism Spectrum Disorder
- see Psychiatry, Neurodevelopmental Disorders, PS39

Motor Delay
- see Cerebral Palsy, P85 and Muscular Dystrophy, P45

Endocrinology

Antidiuretic Hormone

Diabetes Insipidus
- see Endocrinology, E19 and Nephrology, NP11

Syndrome of Inappropriate Antidiuretic Hormone
- see Endocrinology, E19 and Nephrology, NP9

Diabetes Mellitus

DIABETES MELLITUS TYPE 1
- see Disorders of Glucose Regulation, Endocrinology, E7

Epidemiology
- most common form of DM in children, M=F
- variable prevalence internationally, affects ~1:4,000 children in Canada
- can present at any age, but bimodal peaks at 5-7 yr old and at puberty

Clinical Presentation
- can present as polyuria (often manifested as nocturia or secondary enuresis), polydipsia, weight loss (lack of insulin leading to a catabolic state), polyphagia, DKA (~20%) (see Endocrinology, E11)

Management
- patients and families are best managed with a family-centered paediatric multidisciplinary team able to provide education, ongoing care, and psychosocial support surrounding survival skills, meal plans, and insulin injections as a cornerstone of treatment
- blood glucose monitoring is especially important in children as they are more susceptible to hypoglycemia
- if DKA present: ABCs, admit, monitors, correct fluid losses, administer insulin and restore glucose gradually, correct electrolyte disturbances, identify/treat precipitating event, avoid complications (i.e. cerebral edema)
- low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern
- see Endocrinology, E11
- screen for micro- and macrovascular complications (regular ophthalmology assessments, BP, microalbuminuria), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.), and mental health issues (depression, eating disorders)

Diagnostic Criteria for DM (Types 1 and 2) in Children
1. Symptoms (polyuria, polydipsia, weight loss, etc…) & hyperglycemia (Random glucose ≥11.1 mmol/L)
OR,
2. Two of the following on one occasion:
   - Fasting glucose ≥7.0 mmol/L
   - 2 h plasma glucose during OGTT ≥11.1 mmol/L
   - Random glucose ≥11.1 mmol/L (not appropriate for confirmatory testing)
OR
3. One of the following on two separate occasions*
   - Fasting glucose ≥7.0 mmol/L
   - 2 h plasma glucose during OGTT ≥11.1 mmol/L
   - Random glucose ≥11.1 mmol/L (not appropriate for confirmatory testing)

* Random glucose is not appropriate for confirmatory (second) testing
Prognosis
- no cure currently
- short-term complications
  - hypoglycemia
    - due to missed/delayed meals, excess insulin or exercise, illness
    - can lead to seizures and/or coma
    - reversed with PO/IV glucose or IM glucagon
  - hyperglycemia
    - due to intercurrent illness, diet-to-insulin mismatch
    - ↑ risk of end-organ damage
  - DKA: due to missed insulin doses, infection; most common cause of death
- long-term complications
  - microvascular: retinopathy, nephropathy, neuropathy
  - macrovascular: metabolic syndrome, CVD, CAD, PVD
  - increased risk of other autoimmune diseases

DIABETES MELLITUS TYPE 2
- see Family Medicine, FM22, Endocrinology, E7
- impaired glucose metabolism due to increased peripheral insulin resistance
- rare before 10 yr of age, but more common in older children/adolescents
- prevalence is rising mainly due to the increased incidence of childhood obesity
- risk factors: obesity, positive family history, female gender, certain ethnic groups
- clinical presentation may be similar to that of type 1 DM, though most children are asymptomatic
- may present in DKA or hyperglycemic hyperosmotic nonketotic state
- management
  - initiate lifestyle modification program, including diet, weight loss, physical activity
  - glycemic target: HbA1c ≤7%
  - if glycemic targets not achieved within 3-6 mo from diagnosis with lifestyle intervention alone, either metformin, glimepiride, or insulin should be initiated
  - monitor HbA1c every 3 mo
  - advise patient to monitor finger-stick blood glucose levels if on medication with risk of hypoglycemia, are changing medication regimen, have not met treatment goals, or have intercurrent illness
- prognosis: includes microvascular and macrovascular complications similar to type 1 DM

Management of Newly Diagnosed Type 2 DM in Children and Adolescents
Pediatrics 2013;131(2):394-42
Key Action Statements
1. Clinicians should ensure that insulin therapy is initiated for children and adolescents with type 2 DM who are ketotic or in DKA and in whom the distinction between type 1 and 2 DM is unclear and, in usual cases, should initiate insulin therapy for patients
   a. who have random venous or plasma BG concentrations 14 mmol/L, or
   b. whose HbA1c is >9%.
2. Clinicians should initiate a lifestyle modification program, including nutrition and physical activity, and start metformin as first-line therapy for children and adolescents at the time of diagnosis of type 2 DM.
3. The committee suggests that clinicians monitor HbA1c concentrations every 3 mo and intensify treatment if treatment goals for finger-stick BG and HbA1c concentrations are not being met.
4. Clinicians should advise patients to monitor finger-stick BG concentrations in patients who
   a. are taking insulin or other medications with a risk of hypoglycemia; or
   b. are initiating or changing their diabetes treatment regimen; or
   c. have not met treatment goals; or
c. have intercurrent illnesses.
5. Clinicians should incorporate the Academy of Nutrition and Dietetics’ Pediatric Weight Management Evidence-Based Nutrition Practice Guidelines in their dietary or nutrition counselling of patients with type 2 DM at the time of diagnosis and as part of ongoing management.
6. Clinicians should encourage children and adolescents with type 2 DM to engage in moderate-to-vigorous exercise for at least 60 min daily and to limit nonacademic “screen time” to less than 2 h/d.

Growth

APPROACH TO SHORT STATURE

Definition
- short stature: height <3rd percentile
- poor growth evidenced by growth deceleration (height crosses major percentile lines, growth velocity <25th percentile)

Epidemiology
- ~2.5% of the population by definition

Etiology
- see sidebar

Clinical Presentation
- history and physical exam
  - plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS)
  - assess for dysmorphic features, disproportionate short stature
  - risk factors for GH deficiency: previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery
  - decreased growth velocity may be more worrisome than actual height
- investigations
  - calculate mid-parental height: children are usually in a percentile between their parents’ height
  - AP x-ray of left hand and wrist for bone age
  - remaining investigations guided by history and physical (e.g. TSH, sweat chloride, etc.)

4 Questions to Ask when Evaluating Short Stature
- Was there IUGR?
- Is the growth proportionate?
- Is the growth velocity normal?
- Is bone age delayed?
Management
• depends on severity of problem as perceived by parents/child
• no treatment for non-pathological short stature, except for idiopathic short stature
• GH therapy: if administered at an early age, can help patients achieve adult height
  • requirements
    ▪ GH shown to be deficient by 2 different stimulation tests
    ▪ growth velocity <3rd percentile or height <<3rd percentile
    ▪ bone age x-rays show unfused epiphyses/delayed bone age
  • support and management of resultant self-image issues, social anxiety, etc.

Figure 7. Approach to the child with short stature

TALL STATURE
• height greater than two SD above the mean for a given age, sex, and race

Etiology
• constitutional/familial
• endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
• genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome

Hypercalcemia/Hypocalcemia/Rickets
• see Endocrinology, E37

Hyperthyroidism and Hypothyroidism
• may be congenital or acquired (for acquired causes, see Endocrinology, E21)

CONGENITAL HYPERTHYROIDISM
• also known as neonatal Graves’ disease

Epidemiology
• ~1:25,000 neonates, M=F

Etiology
• results from transplacental passage of maternal thyroid stimulating antibodies from mother with a history of Graves’ disease
Clinical Presentation
- history and physical exam
  - clinical manifestations may be masked if mother on antithyroid treatment
  - may present with tachycardia with CHF, heart murmur, goitre, craniosynostosis, irritability, poor feeding, FTT
- investigations:
  - serum levels of TSH and free T4 in all infants with suspected congenital hyperthyroidism or infants born to mothers with Graves’ disease

Management
- methimazole until antibodies cleared
- symptomatic treatment as needed (e.g. β-blockers to control tachycardia)

Prognosis
- if prompt and adequate treatment given, most neonates improve rapidly
- antibodies usually spontaneously cleared by 2-3 mo of life
- fetal or neonatal hyperthyroidism may have adverse effects on CNS development, leading to developmental and behaviour problems

CONGENITAL HYPOTHYROIDISM

Epidemiology
- incidence: 1:4,000-1:20,000 newborn births; F:M = 2:1
- one of the most common preventable causes of intellectual disability

Etiology
- may be classified as permanent primary, central, or transient hypothyroidism
- ~85% of primary cases are sporadic (mostly thyroid dysgenesis), remaining 15% hereditary (mostly inborn errors of thyroid synthesis)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications

Clinical Presentation
- history and physical exam
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - prolonged jaundice, constipation, sluggish, hoarse cry, lethargy, poor feeding, macroglossia, coarse facial features, large fontanelles, umbilical hernia
- investigations
  - diagnosis through newborn screening of TSH or free T4; abnormal results should be confirmed with serum levels from venipuncture

Management
- thyroxine replacement

Prognosis
- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound)

Sexual Development

AMBIGUOUS GENITALIA

Definition
- newborn or child whose gender is difficult to assign based on the appearance of genitalia
- subtype of DSD: a condition in which development of chromosomal, gonadal, or anatomic sex is atypical
- subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

Epidemiology
- incidence of genital abnormalities at birth is as high as 1:300
- prevalence of complex anomalies with true sexual ambiguity much lower at ~1:5,000
Etiology

- **46,XY DSD**
  - inborn error of testosterone biosynthesis or Leydig cell hypoplasia
  - 5-a-reductase deficiency, androgen receptor deficiency or insensitivity
  - LH/hCG unresponsiveness
- **46,XX DSD**
  - virilizing CAH (most common)
  - maternal source: virilizing ovarian or adrenal tumours, untreated maternal CAH, placental aromatase deficiency
- **ovotesticular DSD**
  - both ovarian follicles and seminiferous tubules in the same patient with a 46,XX karyotype
  - mixed gonadal dysgenesis

Risk Factors

- parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/death, or primary amenorrhea, maternal medications during pregnancy (e.g. androgens, progesterones, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

Clinical Presentation

- **history**
  - thorough obstetrical history, including prenatal screens and maternal medications
  - family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern may suggest androgen insensitivity syndrome
- **physical exam**
  - male pseudohermaphrodite (XY): small phallus, hypospadias, undescended testicles
  - female pseudohermaphrodite (XX): clitoral hypertrophy, labioscrotal fusion
  - look for concurrent midline defects, dysmorphic features, and congenital abnormalities
- **investigations**
  - karyotype and genetic workup as indicated
  - blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone, androgens, FSH, and LH
  - imaging: abdominal U/S to look for uterus, testicles, ovaries

Management

- avoid announcement of probable sex or use of personal pronouns until all tests are complete
- continuous psychosocial support for parents and child during development
- elective surgical reconstruction of genitalia is sometimes possible

CONGENITAL ADRENAL HYPERPLASIA

Definition

- autosomal recessive disorder characterized by the partial or total defect of various synthetic enzymes of the adrenal cortex required for cortisol and aldosterone production

Epidemiology

- occurs in ~1:15,000 live births
- most common cause of ambiguous genitalia

Etiology

- for biosynthetic pathways of adrenal cortex, see Endocrinology, E30
- 21-OH responsible for ~95% of CAH cases
- results in ↓ cortisol and aldosterone production with shunting toward ↑ androgens
- cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
- rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH, and 3-HSD

Clinical Presentation

- depends on which enzyme in cortisol synthesis pathway is defective
- presentation of 21-OH deficiency can be divided into
  - classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis
  - classic deficiency without salt wasting: simple virilizing type
  - non-classic: signs/symptoms of androgen excess (e.g. amenorrhea, precocious puberty, etc.)
- 21-OH deficiency screening is part of many newborn screening programs across North America
- high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency
Management
- correct any abnormalities in fluids, electrolytes, or serum glucose
- provide glucocorticoids/mineralocorticoids as necessary, extra glucocorticoids in times of stress
- psychosocial support

Prognosis
- complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT

Physiology
- puberty occurs with the maturation of the HPG axis
- ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids → secondary sexual characteristics
- adrenal production of androgens also required

Females
- onset: age 8-13 yr old (may start as early as 7 yr in girls of African descent)
- usual sequence
  1. thelarche: breast budding
  2. pubarche: axillary hair, body odour, mild acne
  3. growth spurt
  4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
- early puberty is common and often constitutional, late puberty is rare (rule out organic causes)

Males
- onset: age 9-14 yr old
- usual sequence
  1. testicular enlargement
  2. penile enlargement
  3. pubarche: axillary and facial hair, body odour, mild acne
  4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of males during puberty (but any discharge from nipple or fixed mass should be investigated)

Tanner Staging
- scale used in pediatrics that defines physical measurements of development based on external primary and secondary sex characteristics

Figure 8. Tanner staging
PRECOCIOUS PUBERTY

Definition
- development of secondary sexual characteristics 2-2.5 SD before population mean
- <8 yr old for females, <9 yr old for males

Epidemiology
- 1/10,000; F>M

Etiology
- usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- central (GnRH dependent)
  - hypergonadotropic hypergonadism; hormone levels as in normal puberty
  - premature activation of the HPG axis
  - differential diagnosis: idiopathic or constitutional (most common in females), CNS disturbances (tumours, hamartomas, post-meningitis, increased ICP, radiotherapy), NF, primary severe hypothyroidism
- peripheral (GnRH independent)
  - hypogonadotropic hypogonadism
  - differential diagnosis: adrenal disorders (CAH, adrenal neoplasm), testicular/ovarian tumour, gonadotropin/hCG secreting tumour (hepatoblastoma, intracranial teratoma, germinoma), exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely hypothryoidism (Van Wyk-Grumbach syndrome)

Clinical Presentation
- history
  - symptoms of puberty, family history of precocious puberty, medical illness
- physical exam
  - growth velocity
    - prepubertal: 4 to 6 cm/yr
    - growth spurt: boys 8-10 cm/yr, girls 6-8 cm/yr
  - complete physical exam, including Tanner staging and neurological assessment
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, DHEA-S, 17-OH-progesterone)
  - secondary tests: MRI head, pelvic U/S, β-hCG, GnRH, and/or ACTH stimulation test

Management
- indications for medical intervention to delay progression of puberty: rapid advancement of puberty, early age, risk of compromise of final adult height, psychological
- central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists (e.g. leuprolide) most effective
- peripheral causes: goal is to limit effects of elevated sex steroids; treat underlying cause; medications that decrease the production of a specific sex steroid or block its effects (e.g. ketoconazole, spironolactone, tamoxifen, anastrozole), surgical intervention

DELAYED PUBERTY

Definition
- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
- for males: lack of testicular enlargement by 14 yr old
- for females: lack of breast development by 13 yr old OR absence of menarche by 16 yr old or within 5 yr of pubertal onset

Epidemiology
- M>F

Etiology
- usually constitutional delay in males, more suggestive of pathology in females
- central causes
  - constitutional delay in activation of HPG axis (most common)
  - hypogonadotropic hypogonadism
- peripheral causes
  - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)
Clinical Presentation

- history: weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females)
- physical exam: growth velocity (minimum 4 cm/yr), Tanner staging, neurological exam, complete physical exam
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, IGf-1), CBC, electrolytes, BUN, Cr, LFTs, liver enzymes, ESR, CRP, urinalysis
  - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist

Management

- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males

Gastroenterology

Vomiting

History

- characteristic of emesis (e.g. projectile, bilious, bloody)
- pattern of emesis (e.g. association with feeds, cyclic, morning)
- associated symptoms (e.g. anorexia, diarrhea, etc.)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration
- note that vomiting without diarrhea is most likely not gastroenteritis

Physical Findings

- vital signs to determine clinical status and hydration state

Investigations

- CBC, electrolytes, BUN, Cr, amylase, lipase, glucose done routinely
- in sick child, add: ESR, venous blood gases, C&S (blood, stool), imaging

</tbody>
</table>

**Management**
- rehydration (see Fluids and Electrolytes, P76)
- treat underlying cause

### Gastroesophageal Reflux

**Epidemiology**
- extremely common in infancy (up to 50%)

**Clinical Presentation**
- vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)

**Investigations**
- thriving baby requires no investigation
- investigations required if concomitant FTT, feeding aversion, recurrent cough, pneumonia or bronchospasm, GI blood loss or symptoms persist after 18 mo

**Management**
- conservative: thickened feeds, frequent and smaller feeds, elevation of head
- medical
  - short-term parenteral feeding to enhance weight gain
  - ranitidine, PPI: decreases gastric acidity, decreases esophageal irritation
  - domperidone, metoclopramide: improves gastric emptying and GI motility; safety concerns and limited efficacy, should be reserved for children with gastroparesis contributing to GERD
- surgical: indicated for failure of medical therapy (Nissen fundoplication)

**Complications**
- esophagitis, strictures, Barrett’s esophagus, FTT, aspiration, oral feeding aversion
Tracheoesophageal Fistula
• see General Surgery, GS66

Pyloric Stenosis
• see General Surgery, GS63

Duodenal Atresia
• see General Surgery, GS65

Malrotation of the Intestine
• see General Surgery, GS64

Diarrhea
• definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
  • infants → increase in stool frequency to twice as often per day; older children → 3+ loose or watery stools/d
  • duration: acute: <2 wk; chronic: >2 wk

Pathophysiology
• osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
• secretory: increased secretion of Cl⁻ ions and water in intestinal lumen (e.g. bacterial toxin)
• malabsorption: decreased GI surface area (e.g. short bowel syndrome)

History
• frequency, duration, quality of diarrhea
• associated symptoms (e.g. fever, abdominal pain, hematochezia, etc.)
• recent antibiotic use or recent travel
• elements of diet

Physical Findings
• vital signs to determine clinical status and hydration state

Investigations
• acute diarrhea
  • stool for C&S, O&P, electron microscopy for viruses, C. difficile toxin, microscopy (leukocytes suggestive of invading pathogen), blood and urine cultures, blood work
  • chronic diarrhea
  • serial heights, weights, growth percentiles
  • if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
  • red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration
    • require full workup (as per below)
  • stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, C. difficile toxin, 3 d fecal fat, α-1-antitrypsin clearance, fecal elastase
  • urinalysis, urine culture
  • CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, carotene, Ca²⁺, PO₄³⁻, Mg²⁺, Fe, ferritin, folate, fat-soluble vitamins, PTT, INR
  • sweat chloride, celiac screen, thyroid function tests, urine VMA and HVA, HIV test, lead levels
  • CXR, upper GI series and follow-through
  • specialized tests: endoscopy, small bowel biopsy

Diarrhea is defined as an increase in frequency and/or decreased consistency of stools compared to normal
Normal stool volume
Infants: 5-10 g/kg/d
Children: 200 g/d

Diarrhea Red Flags
Bloody stool, fever, petechiae or purpura, signs of severe dehydration, weight loss/FTT

Common Antibiotics that Can Lead to C. difficile Infection
• Fluoroquinolones
• Clindamycin
• Penicillin (broad spectrum)
• Cephalosporins (broad spectrum)
Differential Diagnosis

Gastroenteritis

History
- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- bacterial and parasitic agents more common in older children (2-4 yr)
- recent infectious contacts: symptoms usually begin 24-48 h after exposure

Physical Exam
- febrile
- dehydrated: must assess extent (see Dehydration, P76)

Investigations
- not usually necessary in young children
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology; pH <6 and presence of reducing substances suggests viral etiology

Complications
- viral gastroenteritis usually self-limiting (lasts 3-7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

Table 15. Gastroenteritis

<table>
<thead>
<tr>
<th>Viral Infection</th>

<td>Day care, young age, sick contacts, immunocompromised Bacterial infection: travel, poorly cooked meat, poorly refrigerated foods, antibiotics</td>
</tr>
<tr>
<td>Management</td>
<td>Prevention and treatment of dehydration most important (see Dehydration, P76) Early refeeding advisable, with age-appropriate diet upon completion of rehydration Ondansetron for suspected gastroenteritis with mild to moderate dehydration or failed ORT and significant vomiting Antibiotic or antiparasitic therapy when indicated, antidiarrheal medications not indicated Notify Public Health authorities if appropriate Promote regular hand-washing and return to school 24 h after last diarrheal episode to prevent transmission Rotavirus vaccine</td>
</tr>
</tbody>
</table>
**Toddler’s Diarrhea**

**Epidemiology**
- most common cause of chronic diarrhea during infancy
- onset between 6-36 mo of age, ceases spontaneously between 2-4 yr

**Clinical Presentation**
- diagnosis of exclusion in thriving child
- 4-6 bowel movements per day
- diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
- stool may contain undigested food particles
- excoriated diaper rash

**Management**
- reassurance that it is self-limiting
- 4Fs (adequate fibre, normal fluid intake, 35-40% fat, discourage excess fruit juice)

**Lactase Deficiency (Lactose Intolerance)**

**Clinical Presentation**
- chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
- primary lactose intolerance: crampy abdominal pain with loose stool (older children, usually of East Asian and African descent)
- secondary lactose intolerance: older infant, persistent diarrhea (post viral/bacterial infection, celiac disease, or IBD)

**Diagnosis**
- trial of lactose-free diet
- watery stool, acid pH, positive reducing sugars
- positive breath hydrogen test if >6 yr

**Management**
- lactose-free diet, soy formula
- lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

**Irritable Bowel Syndrome**
- see Gastroenterology, G23

**Celiac Disease**
- see Gastroenterology, G18
- in children: presents at any age, usually 6-24 mo with the introduction of gluten in the diet
- FTT with poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks, rarely distended abdomen
- GI symptoms: anorexia, N/V, edema, anemia, abdominal pain
- non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioural changes
- associated with other autoimmune disorders

**Milk Protein Allergy**

**Pathophysiology**
- immune-mediated mucosal injury (IgE- and non-IgE-mediated)

**Clinical Presentation**
- up to 50% of children intolerant to cow’s milk may be intolerant to soy protein as well
- often history of atopy
- can present as
  - proctocolitis: mild diarrhea, small amounts of bloody stools (common presentation in young infant)
  - enterocolitis: vomiting, diarrhea, anemia, hematochezia
  - enteropathy: chronic diarrhea, hypoalbuminemia

A Celiac disease diet must avoid gluten present in “BROW” foods
Barley
Rye
Oats (controversial)
Wheat

Celiac disease is associated with an increased prevalence of IgA deficiency. Since tTG is an IgA-detecting test, you must order an accompanying IgA level.
Management
• casein hydrolysate formula (dairy-free e.g. Nutramigen®, Pregestimil®) or mother may remove all milk protein from diet and continue breastfeeding (with adequate calcium and vit D intake)
• often outgrow by 1 yr of age

Inflammatory Bowel Disease
• see Gastroenterology, G19

Cystic Fibrosis
• see Respirology, P90

Constipation
• decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION
• 99% of cases of constipation
• Rome III criteria; ≥2 of the following
  ▪ ≤2 defecations in the toilet/wk
  ▪ ≥1 episode of fecal incontinence/wk
  ▪ history of retentive posturing or excessive volitional stool retention
  ▪ history of painful or hard bowel movements
  ▪ large fecal mass in rectum
  ▪ history of large diameter stools that may obstruct toilet

Pathophysiology
• lack of fibre in diet or change in diet, poor fluid intake, behavioural
  ▪ infants: often occurs when introducing cow’s milk after breast milk due to high fat and solute content, lower water content
  ▪ toddlers/older children: can occur during toilet training, or due to pain on defecation, leading to withholding of stool
  ▪ two crucial time periods: toilet training and starting school

Management
• education: explanation of mechanism of functional constipation for parents/older children
• clean out: PEG 3350 flakes (1-1.5 g/kg/d, max 100 g/d), picosalax, PEGlyte®
• maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fibre (fruit, vegetables, whole grains), stool softening (PEG 3350, mineral oil), appropriate toilet training technique (dedicated time for defecation: 3-10 min, 1-2 x/d)
• children should be treated for at least 6 mo, and should not be weaned from maintenance therapy until they are having regular bowel movements without difficulty
• regular follow-up with ongoing support and encouragement is essential

Complications
• pain retention cycle: anal fissures + pain → withhold passing stool → chronic dilatation ± overflow incontinence

HIRSCHSPRUNG’S DISEASE (Congenital Aganglionic Megacolon)
• see General Surgery, GS65

OTHER ORGANIC DISORDERS CAUSING CONSTIPATION
• endocrine: hypothyroidism, DM, hypercalcemia
• neurologic: spinal cord abnormalities/trauma, NF
• anatomic: bowel obstruction, anus (imperforate, atresia, stenosis, anteriorly displaced)
• drugs: lead, chemotherapy, opioids
• others
Abdominal Pain

ACUTE ABDOMINAL PAIN

History
• description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
• associated symptoms: N/V, diarrhea, fever

Physical Exam
• abdominal exam, rectal exam, rash

Investigations
• CBC, differential, urinalysis to rule out UTI

Table 16. Differential Diagnosis of Acute Abdominal Pain

</tbody>
</table>
• see General Surgery, GS28
• most common cause of acute abdomen after 5 yr of age
• clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
• treatment: surgical
• complications: perforation (common in young children), abscess

INTUSSUSCEPTION
• telescoping of segment of bowel into distal segment causing ischemia and necrosis

Epidemiology
• 90% idiopathic, children with CF or GJ tube at significantly increased risk; M:F = 3:1
• 50% between 3-12 mo, 75% before 2 yr of age

Pathophysiology
• usual site: ileocecal junction; jejunum in children with GJ tubes
• lead point of telescoping segment may be swollen Peyer’s patches, Meckel’s diverticulum, polyp, malignancy, HSP, structural abnormalities

Clinical Presentation
• “classic triad” (<25% patients) - abdominal pain, palpable mass, red currant jelly stools
• often preceded by URTI
• sudden onset of recurrent, paroxysmal, severe periumbilical pain with pain-free intervals
• later vomiting (may be bilious) and rectal bleeding (late finding)
• shock and dehydration; lethargy may be only presenting symptom

Diagnosis
• U/S, air enema

Management
• air enema can be therapeutic (reduces intussusception in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed
• recurrence rate 10-15%, need to consider pathologic lead point
### Chronic Abdominal Pain

#### Epidemiology
- prevalence: 10% of school children (peak at 8-10 yr), F>M

#### Etiology
- organic (<10%)
  - gastrointestinal
    - constipation (cause vs. effect), infectious
    - IBD, esophagitis, peptic ulcer disease, lactose intolerance
  - anatomic anomalies, masses
  - pancreatic, hepatobiliary
  - genitourinary causes: recurrent UTI, nephrolithiasis, chronic PID, Mittelschmerz
  - neoplastic
- functional abdominal pain (90%): can be diagnosed when there are no alarm symptoms or signs, physical exam is normal, and stool sample tests are negative for occult blood; no further testing is required, unless high suspicion for organic cause

#### Clinical Presentation
- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

#### Investigations
- fecal occult blood and others based on clinical suspicion (CBC, ESR, urinalysis, etc.)

#### Management
- continue to attend school
- manage any emotional or family problems, counselling, CBT
- trial of high fibre diet, trial of lactose-free diet
- possible role for amitriptyline
- reassurance

#### Prognosis
- pain resolves in 30-50% of children within 2-6 wk of diagnosis
- 30-50% of children with functional abdominal pain have functional pain as adults (e.g. IBS)

### Abdominal Mass

#### Table 17. Differential Diagnosis for Abdominal Mass

### Upper Gastrointestinal Bleeding
- see Gastroenterology, G25
Lower Gastrointestinal Bleeding

• see Gastroenterology, G27

Etiology
• acute
  ▪ infectious (bacterial, parasitic)
  ▪ antibiotic-induced (C. difficile)
  ▪ NEC in preterm infants
  ▪ anatomic
  ▪ malrotation/volvulus, intussusception
  ▪ Meckel's diverticulitis
  ▪ anal fissures, hemorrhoids
  ▪ vascular/hematologic
  ▪ HSP
  ▪ HUS
  ▪ coagulopathy

• chronic
  ▪ anal fissures (most common)
  ▪ colitis
  ▪ IBD
  ▪ allergic (milk protein)
  ▪ structural
  ▪ polyps (most are hamartomas)
  ▪ neoplasms (rare)
  ▪ coagulopathy

Physical Exam
• hemodynamic status, evidence of FTT, fever
• anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
• stool appearance
• NG aspirate
• lower GI bleed may present as melena (if it involves the small bowel) or hematochezia

Investigations
• stool cultures (C&S, C. difficile toxin)
• urinalysis and microscopy
• CBC, smear, differential, ESR, CRP, electrolytes, urea, Cr, INR, PTT, albumin, iron studies, amoeba titers
• radiologic investigations (including abdominal x-ray to rule out obstruction)
• Meckel's radionuclide scan

Management
• acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
• once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms, and Metabolism

Genetics

MECHANISMS OF INHERITANCE

Mendelian Inheritance
• disorders caused by mutation of one or both copies of a gene, inherited in one of two patterns
  ▪ autosomal: encoded by genes on one of 22 pairs of autosomes (chromosomes 1-22)
  ▪ X-linked: encoded by a gene on the X chromosome

Triplet Repeat Expansions
• disorder in which trinucleotide repeats in certain genes exceed the normal number and result in altered expression of the gene or production of an abnormal protein (e.g. Fragile X syndrome, spinocerebellar ataxias, myotonic dystrophy, Huntington disease)

Imprinting Disorders
• imprinting: epigenetic process that involves methylation or acetylation of DNA, affecting gene expression
• imprinted genes are expressed differently depending on whether they are inherited from the mother or the father (parent-of-origin gene expression)
• occur when imprinted alleles are silenced (e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome)

Mitochondrial Inheritance
• disorders caused by mutations of the DNA present in mitochondria
• inheritance pattern: mother passes on the defect to all her children; father does not pass on the defect since embryo only receives mitochondria from the mother (in the egg)
METHODS OF GENETIC TESTING

- microarray analysis
  - a microarray is a collection of DNA probes attached to a solid surface
  - microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome
  - indicated when there is developmental delay + one or more major malformations
- FISH: usually to identify a gain or loss of chromosomal material
- karyotype: microscopic analysis of all 46 chromosomes with a special stain that shows large changes in the number or structure of chromosomes

Genetic Anomalies

Minor and Major Anomalies

- minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
- major anomaly: anomaly that creates significant medical, surgical, or cosmetic problems for the patient

Mechanism for Anomalies

- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. bone dysplasia)

Multiple Anomalies

- association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not believed to have a single etiology (e.g. VACTERL)
- sequence: related anomalies that come from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence)
- syndrome: a pattern of anomalies that occur together and are caused by a single known or unknown cause (e.g. Down syndrome)

Approach to the Dysmorphic Child

- genetic disorders are the most common cause of infant death in developed countries

General Approach to the Dysmorphic Child

- Are the anomalies major or minor?
- What is the mechanism underlying the anomaly?
- Do the anomalies fit as part of an association, sequence, or syndrome?

History

- prenatal/obstetrical history (see Obstetrics, OB4) with particular attention to potential teratogenic exposures
- complete 3 generation family pedigree: consanguinity, stillbirths, neonatal deaths, specific illnesses, intellectual disability, multiple miscarriages, ethnicity
**Physical Exam**

**Investigations**
- screening for TORCH infections
- serial photographs if child is older
- x-rays for bony abnormalities
- cytogenetic studies
  - karyotype if recognized syndrome
  - chromosome microarray analysis (array comparative genomic hybridization) if developmental delay with one or more congenital anomalies
  - FISH if microdeletion syndrome or trisomy suspected
- biochemistry: specific enzyme assays
- single gene testing

**Management**
- prenatal counselling and assessing risk of recurrence
- referral for specialized pediatric or genetic care

**Genetic Syndromes**

**DUCHENNE MUSCULAR DYSTROPHY**

**Epidemiology**
- 1:4,000 males

**Etiology**
- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) → muscle fibre fragility → fibre breakdown → necrosis and regeneration

**Clinical Presentation**
- proximal muscle weakness by age 3, positive Gower’s sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

**Diagnosis**
- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, EMG

**Management**
- supportive (e.g. physiotherapy, wheelchairs, braces), prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

**Complications**
- patient usually wheelchair-bound by 12 yr of age
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in 2nd-3rd decade

**Metabolic Diseases**
- inherited disorders of metabolism; often autosomal recessive
- infants and older children may present with FTT or developmental delay
- universal newborn screening in Ontario includes metabolic disorders

**Metabolic disease must be ruled out in any newborn who becomes acutely ill after a period of normal behaviour and development or with a family history of early infant death even if the newborn screen is negative**

</tbody>
</table>

Initial Investigations
- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, ABGs (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)
- lactate, ammonium (hyperammonemia with urea cycle defects), plasma Ca\(^{2+}\) and Mg\(^{2+}\)
- routine urinalysis: ketonuria must be investigated
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, plasma amino acid screen, urine organic acids, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)
- storage diseases: urine mucopolysaccharide and oligosaccharide screen

Treatment
- varies according to inborn error of metabolism
- dietary restrictions, supplementation, enzyme replacement therapy, gene therapy, liver transplant, stem cell transplant

PHENYLKETONURIA

Epidemiology
- 1:10,000; autosomal recessive disease

Etiology
- deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build up of toxic metabolites
- mothers who have PKU may have infants with congenital abnormalities

Clinical Presentation
- baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors, and mental retardation
- hypopigmentation due to low tyrosine (fair hair, blue eyes)

Management
- PKU screening at birth
- dietary restriction of phenylalanine starting within the first 10 d of life
- duration of dietary restriction controversial – lifelong or until end of puberty; should be resumed during pregnancy to maintain normal phenylalanine levels
GALACTOSEMIA

Epidemiology
- 1:60,000; autosomal recessive disease

Etiology
- most commonly due to deficiency of galactose-1-phosphate uridyltransferase leading to an inability to process lactose/galactose

Clinical Presentation
- signs of liver and renal failure, jaundice, FTT, and cataracts with ingestion of lactose/galactose

Management
- elimination of galactose from the diet (e.g. dairy, breast milk)
- most infants are fed a soy-based diet

Complications
- increased risk of sepsis, especially E. coli
- if the diagnosis is not made at birth, liver and brain damage may become irreversible

Hematology

Approach to Anemia

Figure 10. Approach to anemia

Physiologic Anemia
- high Hb (>170 g/L) and reticulocyte count at birth is caused by a hypoxic environment in utero
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O₂ rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk age (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
- usually no treatment required

Iron Deficiency Anemia
- most common cause of childhood anemia
- full term infants exhaust iron reserves by 6 mo of age
- premature infants have lower reserves, therefore exhausted by 2-3 mo of age
- common diagnosis between 6 mo-3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diet and menstrual losses

Etiology
- children at risk (premature, LBW, low SES, etc.)
- dietary risk factors: whole cow milk in first year of life
• age >6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
• age <12 mo: use of low-iron formula (<10 mg/L), primary diet of cow, goat, or soy milk
• age 1-5 yr: >16-20 oz/d of non-fortified milk
• blood loss
  ▪ iatrogenic: repeated blood sampling (especially in hospitalized neonates)
  ▪ allergic: cow milk protein-induced colitis

**Clinical Manifestation**

• usually asymptomatic until marked anemia, pallor, fatigue, pica (eating non-food materials), tachycardia, systolic murmur, angular cheilitis, koilonychias

**Investigations**

• CBC: low Hb, MCV, and MCH, reticulocyte count normal or high (absolute number low)
  ▪ Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
    ▪ ratio <13 suggests thalassemia; ratio >13 suggests iron deficiency
  ▪ blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
  ▪ iron studies: low ferritin, other (low iron, high total iron binding capacity, high transferrin, low transferrin saturation)
  ▪ initial therapy: trial of iron

**Prevention**

• breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able to eat ≥2 feeds/d of iron-rich foods
• non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
• premature infants: give iron supplements from 1 mo through to 1 yr of age
• no cow’s milk until 9-12 mo, early introduction of red meat and iron-rich vegetables: total daily iron should be 11 mg (age 6-12 mo), 7 mg (age 1-3 yr)
• universal screening of Hb levels recommended at 9 mo

**Management**

• encourage diverse, balanced diet, limit homogenized milk to 16-20 oz/d
• oral iron therapy: 6 mg/kg/d elemental iron, divided bid to tid, for 3 mo
  ▪ increased reticulocyte count in 2-3 d (peaks day 5-7)
  ▪ increased hemoglobin in 4-30 d
  ▪ repletion of iron stores in 1-3 mo
  ▪ repeat hemoglobin levels after 1 mo of treatment
• poor response to oral iron therapy: non-compliance, medication intolerance, ongoing blood loss, IBD, celiac disease, incorrect diagnosis

**Complications**

• can cause irreversible effects on development if untreated (behavioural and intellectual deficiencies)
• angular cheilitis, glossitis, koilonychia (spoon nails)

**Vitamin K Deficiency**

• hemorrhagic disease of the newborn due to relative deficiencies of vitamin K-dependent coagulation factors
  ▪ generalized bleeding; GI/intracranial hemorrhage
• IM injection at birth, can also be given orally (3 doses: at birth, 2-4 wk, 6-8 wk) but infants at higher risk of HDNB
• reason for administration at birth:
  ▪ human milk contains small amounts of vitamin K, and infants require ingestion of large volumes of human milk to promote GI bacterial colonization
  ▪ until few days after birth, susceptible to vitamin K deficiency

DIC = disseminated intravascular coagulation; PFA = platelet function assay; VIII:C = Factor VIII coagulant activity; vWF = von Willebrand Factor

Immune Thrombocytopenic Purpura

Epidemiology
- most common cause of thrombocytopenia in childhood
- peak age: 2-6 yr, M=F
- incidence 5:100,000 children per year

Etiology
- caused by autoantibodies that bind to platelet membranes → Fc-receptor mediated splenic uptake → destruction of platelets

Clinical Presentation
- 50% present 1-3 wk after viral illness (URTI, chicken pox)
- sudden onset of petechiae, purpura, epistaxis in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only if atypical presentation (≥1 cell line abnormal, hepatosplenomegaly)
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), autoimmune (SLE, ALPS)

Management
- observation vs. pharmacologic intervention highly debated; spontaneous recovery in >70% of cases within 3 mo
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at risk of significant bleeding (surgery, dental procedure, concomitant vasculitis or coagulopathy)
- life-threatening bleed: additional platelet transfusion ± emergency splenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

Hemophilia

- see Hematology, H31
von Willebrand’s Disease

- see Hematology, H30

Oncology

- cancer is the second most common cause of death after injuries in children after 1 yr of age
- cause is rarely known, but increased risk for children with: chromosomal syndromes (e.g. Trisomy 21), prior malignancies, neurocutaneous syndromes, immunodeficiency syndromes, family history, exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of pediatric malignancy (30%) followed by brain tumours (25%), and lymphomas (15%)
- some malignancies are more prevalent in certain age groups
  - newborns: neuroblastoma, Wilms’ tumour, retinoblastoma
  - infancy and childhood: leukemia, neuroblastoma, CNS tumors, Wilms’ tumour, retinoblastoma
  - adolescence: lymphoma, gonadal tumours, germ cell tumours, bone tumours
- unique treatment considerations in pediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function, and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many pediatric cancers (>80%)

Lymphadenopathy

Clinical Presentations

- features of malignant lymphadenopathy: firm, discrete, non-tender, enlarging, immobile ± suspicious mass/imaging findings ± constitutional symptoms
- fluctuance, warmth, or tenderness are more suggestive of benign nodes (infection)

Differential Diagnosis

- infection
  - viral: URTI, EBV, CMV, adenovirus, HIV
  - bacterial: S. aureus, GAS, anaerobes, Mycobacterium (e.g. TB), cat scratch disease (Bartonella)
    - other: fungal, protozoan, Rickettsia
  - autoimmune: rheumatoid arthritis, SLE, serum sickness
  - malignancy: lymphoma, leukemia, metastatic solid tumours
  - storage diseases: Niemann-Pick, Gaucher’s
  - other: sarcoidosis, Kawasaki disease, histiocytoses

Investigations

- generalized lymphadenopathy
  - CBC and differential, blood culture
  - uric acid, LDH
  - ANA, RF, ESR
  - EBV/CMV/HIV serology
  - toxoplasma titre
  - fungal serology
  - CXR
  - TB tests
  - biopsy
- regional lymphadenopathy
  - period of observation if asymptomatic
  - trial of oral antibiotics
  - ultrasonad
  - biopsy (especially if persistent >6 wk and/or constitutional symptoms)

Leukemia

- see Hematology, H37

Epidemiology

- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases
  - ALL (80%)
  - AML (15%)
  - CML (<5%)
- children with DS are 15x more likely to develop leukemia

Clinical Presentation

- infiltration of leukemic cells into bone marrow results in bone pain and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease

Most common cause of acute bilateral cervical LAD is viral illness
• fever, fatigue, weight loss, bruising, and easy bleeding
• hyperleukocytosis (total WBC >100 x 10^9/L) is a medical emergency
  ▪ presents clinically with respiratory or neurological distress caused by hyperviscosity of blood and leukostasis
  ▪ risk of ICH, pulmonary leukostasis syndrome, tumour lysis syndrome
• management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)

Management
• combination chemotherapy using non-cross resistant chemotherapy agents, allogeneic stem cell transplantation for high-grade or recurrent disease
• supportive care and management of treatment complications
  ▪ febrile neutropenia: see Infectious Diseases, ID45
  ▪ tumour lysis syndrome: see Hematology, H52

Prognosis
• 80-90% 5 yr event-free survival for ALL, 50-60% 5-yr survival for AML
• patients are stratified into standard risk and high risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma
• see Hematology, H44

Epidemiology
• Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr old
• non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Clinical Presentation
• Hodgkin lymphoma
  ▪ most common presentation is persistent, painless, firm, cervical or supraclavicular lymphadenopathy
  ▪ can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary, or inguinal lymphadenopathy
  ▪ constitutional symptoms in 30% of children
  ▪ lymph nodes become sequentially involved as disease spreads
• non-Hodgkin lymphoma
  ▪ generally categorized into lymphoblastic, large cell, and Burkitt’s/Burkitt’s-like lymphoma
  ▪ rapidly growing tumour with distant metastases (unlike adult non-Hodgkin lymphoma)
  ▪ signs and symptoms related to disease site: most commonly abdomen, chest (mediastinal mass), head and neck region

Management
• Hodgkin lymphoma
  ▪ combination chemotherapy and radiation
  ▪ aimed at limiting cumulative doses of anthracyclines (toxic to heart) and alkylators (risk of second malignancy, infertility) and limiting dose and field of radiation
  ▪ increasing role for use of PET scanning to assess early disease response and plan therapy
• non-Hodgkin lymphoma
  ▪ combination chemotherapy
  ▪ no added benefit of radiation in pediatric protocols

Prognosis
• Hodgkin lymphoma: >90% 5 yr survival
• non-Hodgkin lymphoma: 75-90% 5 yr survival

Brain Tumours
• see Neurosurgery, NS37

Wilms’ Tumour (Nephroblastoma)

Epidemiology
• usually diagnosed between 2-5 yr; M=F
  ▪ most common primary renal neoplasm of childhood
  ▪ 5-10% of cases both kidneys are affected (simultaneously or in sequence)

Differential Diagnosis
• hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma
Clinical Presentation
- 80% present with asymptomatic, unilateral abdominal mass
- may also present with HTN, gross hematuria, abdominal pain, vomiting
- may have pulmonary metastases at time of diagnosis (respiratory symptoms)

Associated Congenital Abnormalities
- WAGR syndrome (Wilms' tumour, Aniridia, Genital anomalies, mental Retardation) with 11p13 deletion:
  - characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
  - also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumours, neuroblastomas, and rhabdomyosarcomas
- Denys-Drash syndrome: characterized by gonadal dysgenesis and nephropathy leading to renal failure

Management
- staging ± nephrectomy
- chemotherapy, radiation for higher stages

Prognosis
- 90% long-term survival

Neuroblastoma

Epidemiology
- most common cancer occurring in first year of life
- neural crest cell tumour arising from sympathetic tissues (neuroblasts)

Clinical Presentation
- can originate from any site in sympathetic nervous system, presenting as mass in neck, chest, or abdomen (most common site is adrenal gland)
- signs and symptoms of disease vary with location of tumour:
  - thoracic: dyspnea, Horner's syndrome
  - abdominal: palpable mass
  - spinal cord compression
- metastases are common at presentation (>50% present with advanced stage disease):
  - usually to bone or bone marrow (presents as bone pain, limp)
  - can also present with periorbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, "blueberry muffin" skin nodules
  - paraneoplastic: HTN, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus
- diagnostic criteria (either of the following):
  - unequivocal histologic diagnosis from tumour tissue biopsy
  - evidence of metastasis to bone marrow ("rosettes") on aspirate analysis, with concomitant elevation of urine or serum catecholamine metabolite (VMA, HVA) levels

Management
- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, autologous stem cell transplantation, immunotherapy

Prognosis
- prognosis is often poor due to late detection
- good prognostic factors:
  - "age and stage" are important determinants of better outcome: 12-18 mo, stage I, II, IV-S disease ("S" designates a "Special" classification only pertaining to infants)
  - primary site: posterior medias tinum and neck
  - low serum ferritin
  - specific histology
  - tumour cell markers: aneuploidy, absent MYCN oncogene amplification

Bone Tumours
- see Orthopedics, OR46
Infectious Diseases

Fever

Definition
- fever: a practical definition is >38°C/100.4°F oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown origin: daily or intermittent fevers for at least 2 consecutive weeks of uncertain cause after careful history and physical, and initial laboratory assessment

Etiology
- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: dehydration, drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

Diagnosis
- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, recent antipyretic use, ethnic or genetic background, day care, sick contacts, travel, tick bites, age of child
- physical exam: toxic vs. non-toxic, vitals, growth, complete exams of the skin, HEENT, chest, abdomen, lymph nodes, genitalia
- investigations: guided by history, physical exam, and clinical suspicion

Evaluation of Neonates and Infants with Fever
- several protocols exist that attempt to identify neonates and young infants at low risk of serious bacterial infection (e.g. Rochester Criteria)
  - such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high risk regardless of clinical presentation and laboratory findings

Management
- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea, etc.); maintenance fluid needs are higher in febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics (acetaminophen and/or ibuprofen) are not necessary in most cases, but can be given if child is uncomfortable

Figure 11. Approach to the febrile child

Rochester Criteria – Developed to Identify Infants ≤60 d of Age with Fever at Low Risk of Serious Bacterial Infection

NOTES
1. Full Septic Workup (SWU) – blood C&S, CBC and differential, urine R&M, C&S, LP, CXR if respiratory symptoms, stool C&S if GI symptoms
2. Follow-up is crucial – if adequate follow-up is not assured, a more aggressive diagnostic and therapeutic approach may be indicated
3. Low-risk (Rochester) criteria
4. Considerable practice variation exists in terms of empiric antibiotic treatment
5. Important principles – the younger the child, the greater the difficulty to clinically assess the degree of illness
Acute Otitis Media

Definition
All of:
1. presence of middle ear effusion
2. presence of middle ear inflammation
3. acute onset of symptoms of middle ear effusion and inflammation

Epidemiology
- 60-70% of children have at least 1 episode of AOM before 3 yr of age
- 18 mo-6 yr most common age group
- peak incidence January to April
- one third of children have had ≥3 episodes by age 3

Etiology
- *H. influenzae* (non-typeable): >50% of refractory AOM
- *S. pneumoniae*: 32% of cases (incidence decreasing due to pneumococcus vaccine)
- *M. catarrhalis*: 14% of cases
- *S. aureus* and *S. pyogenes* (all β-lactamase producing)
- anaerobes (newborns)
- Gram-negative enterics (infants)
- viral

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - swelling of tubal mucosa: URTI, allergic rhinitis, chronic rhinosinusitis
  - obstruction/infiltration of Eustachian tube ostium: adenoid hypertrophy (not due to obstruction but by maintaining a source of infection), barotrauma (sudden changes in air pressure)
  - inadequate tensor palatini function: cleft palate (even after repair)
  - abnormal Eustachian tube: DS (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
- disruption of action of
  - cilia of Eustachian tube: Kartagener’s syndrome
  - mucus secreting cells
  - capillary network that provides humoral factors, neutrophils, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, CF

Risk Factors
- bottle feeding, pacifier use
- second-hand smoke
- crowded living conditions (day care/group child care facilities) or sick contacts
- male
- family history
- craniofacial abnormalities
- immunodeficiency
- ethnicity

Pathogenesis
- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers: ear-tugging (this alone is not a good indicator of pathology), hearing loss, balance disturbances (rare), irritable, poor sleeping, vomiting and diarrhea, anorexia
- otoscopy of TM: hyperemia, bulging, pus may be seen behind TM, loss of landmarks (e.g. handle and long process of malleus not visible)

Diagnosis
- bulging TM (based on pneumatic otoscopy or tympanometry) is required for the diagnosis of AOM

Management
- 1st line
  - amoxicillin 75-90 mg/kg/d divided into two doses: safe, effective, and inexpensive
  - if penicillin allergic: macrolide (clarithromycin, azithromycin – high resistance), trimethoprim-sulphamethoxazole (Bactrim*)
• 2nd line
  ▪ amoxicillin-clavulanic acid (Clavulin®)
  ▪ cephalosporins: cefuroxime axetil (Ceftin®), ceftriaxone (Rocephin®), cepaclor (Ceclor®), cefixime (Suprax®)
  ▪ AOM deemed unresponsive if clinical signs/symptoms and otoscopic findings persist beyond 48 h of antibiotic treatment
• symptomatic therapy: antipyretics/analgesics (e.g. acetaminophen), decongestants (may relieve nasal congestion but does not treat AOM)
• prevention: parent education about risk factors, pneumococcal and influenza vaccines, surgery (e.g. tympanostomy tubes)
  ▪ choice of surgical therapy for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinusitis) are responsible

Complications
• extracranial: hearing loss and speech delay (secondary to persistent middle ear effusion), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
• intracranial: meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

Otitis Media with Effusion

Definition
• presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
• most common cause of pediatric hearing loss
• not exclusively a pediatric disease
• follows AOM frequently in children
• middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%

Risk Factors
• same as AOM

Clinical Features
• conductive hearing loss ± tinnitus
• fullness – blocked ear
• ± pain, low grade fever
• otoscopy of TM
  ▪ discoloration – amber or dull grey
  ▪ meniscus fluid level behind TM
  ▪ air bubbles
  ▪ retraction pockets/TM atelectasis
  ▪ flat tympanogram
  ▪ most reliable finding with pneumatic otoscopy is immobility

Treatment
• expectant: 90% resolve by 3 mo
• document hearing loss with audiogram (see Otolaryngology Figure 16B and Figure 17B, OT10-11)
• no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
• surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes a few months after first set falls out)
• ventilation tubes to equalize pressure and drain ear

Complications of OME
• hearing loss, speech delay, learning problems in young children
• chronic mastoiditis
• ossicular erosion
• cholesteatoma especially when retraction pockets involve pars flaccida
• retraction of tympanic membrane, atelectasis, ossicular fixation

Gastroenteritis
• see Gastroenterology, P36

HIV Infection

</tr>
</tbody>
</table>
Infectious Mononucleosis

Definition
- systemic viral infection caused by EBV with multivisceral involvement; often called “the great imitator”

Epidemiology
- peak incidence between 15-19 yr old
- ~50% of children in developed countries have a primary EBV infection by 5 yr old, but <10% of children develop clinical infection

Etiology
- EBV: a member of herpesviridae
- transmission is mainly through infected saliva (“kissing disease”) and sexual activity (less commonly); incubation period of 1-2 mo

Risk Factors
- infectious contacts, sexually active, multiple sexual partners in the past

History
- prodrome: 2-3 d of malaise, anorexia
- infants and young children: often asymptomatic or mild disease
- older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

Physical Exam
- classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periorbital edema, ± rash (urticarial, maculopapular, or petechial) – more common after inappropriate treatment with β-lactam antibiotics
- any “-itis” (including arthritis, hepatitis, nephritis, myocarditis, meningitis, encephalitis, etc.)

Investigations
- heterophil antibody test (Monospot® test)
  - 85% sensitive in adults and older children, but only 50% sensitive if <4 yr of age
  - false positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titres
- CBC and differential, blood smear: atypical lymphocytes, lymphocytosis, Downey cells ± anemia ± thrombocytopenia
- throat culture to rule out streptococcal pharyngitis

Management
- supportive: adequate rest, hydration, saline gargles, and analgesics for sore throat
- splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- if airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy
- acyclovir does NOT reduce duration of symptoms or result in earlier return to school/work

Prognosis
- most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- short-term complications: splenic rupture, Guillain-Barré syndrome

Infectious Pharyngitis/Tonsillitis

Definition
- inflammation of the pharynx, especially the tonsils if present, causing a sore throat

Etiology
- viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV
- bacterial (~20%): mainly GAS, M. pneumoniae (older children), N. gonorrhoeae (sexually active), C. diphtheriae (unvaccinated)
- fungal: Candida

Epidemiology
- season: GAS pharyngitis more common in late winter or early spring; viral all year long
- age: GAS pharyngitis peak incidence at 5-12 yr of age and uncommon <3 yr; viral pharyngitis affects all ages

History
- GAS: sore throat (may be severe), fever, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms
- viral: sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgias)
Physical Exam
- GAS: febrile, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
- viral: afebrile, absent/mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

Investigations
- no single sign or symptom reliably identifies GAS as the causative organism in children with sore throat
- scores are used to predict if throat culture will be positive (e.g. McIsaac Criteria)
  - these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
- suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

Management
- antibiotics (for GAS/S. pyogenes)
  - penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
  - can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal GN
- supportive: hydration and acetaminophen for discomfort due to pain and/or fever
- follow-up: if uncomplicated course, no follow-up or post-antibiotic throat cultures needed
- prophylaxis: consider tonsillectomy for proven, recurrent streptococcal tonsillitis

Complications
- preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
- immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal GN, reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A Streptococci (i.e. PANDAS)

SCARLET FEVER
- diffuse erythematous eruption
- delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by GAS
- acute onset of fever, sore throat, strawberry tongue
- 24–48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia's lines may be accentuated in flexural areas
- within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
- rash fades after 3-4 d, may be followed by desquamation
- treatment is penicillin, amoxicillin, or erythromycin x 10 d

RHEUMATIC FEVER
- inflammatory disease due to antibody cross-reactivity following GAS infection
- affects ~1:10,000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr of age
- mainly a clinical diagnosis based on Jones Criteria (revised)
  - requires 2 major OR 1 major and 2 minor PLUS evidence of preceding strep infection (history of scarlet fever, GAS pharyngitis culture, positive rapid Ag detection test, ASOTs)
- treatment: penicillin or erythromycin for acute course x 10 d, prednisone if severe carditis
- secondary prophylaxis with daily penicillin or erythromycin
- complications
  - acute: myocarditis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute MR), pericarditis
  - chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
- onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever

POST-STREPTOCOCCAL GLOMERULONEPHRITIS
- most common in children aged 4-8 yr old; M>F
- antigen-antibody mediated complement activation with diffuse, proliferative GN
- occurs 1-3 wk following initial GAS infection (skin or throat)
- clinical presentation varies from asymptomatic, microscopic and macroscopic hematuria (coloured urine) to all features of nephritic syndrome (see P80)
- diagnosis is confirmed with elevated serum antibody titres against streptococcal antigens (ASOT, anti-DNAse B), low serum complement (C3)
- management
  - symptomatic: fluid and sodium restrictions; loop diuretics for HTN and edema
  - in severe cases, may require dialysis if renal function significantly impaired
  - treat with penicillin or erythromycin if evidence of persistent GAS infection
- 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria
Meningitis

Definition
• inflammation of the meninges surrounding the brain and spinal cord

Epidemiology
• peak age: 6-12 mo; 90% of cases occur in children <5 yr old

Etiology
• viral: enteroviruses, HSV
• bacterial: age-related variation in specific pathogens
• fungal and parasitic meningitis also possible
• most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors
• unvaccinated
• immunocompromised: asplenia, DM, HIV, prematurity
• recent or current infections: AOM, sinusitis, orbital cellulitis
• neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
• exposures: day care centres, household contact, recent travel

History
• signs and symptoms variable and dependent on age, duration of illness, and host response to infection
• infants: fever, lethargy, irritability, poor feeding, vomiting, diarrhea, respiratory distress, seizures
• children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical Exam
• infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/purpuric rash, jaundice
• children: toxic, LOC, nuchal rigidity, Kernig's and Brudzinski's signs, focal neurologic findings, petechial/purpuric rash

Investigations
• blood work: CBC, electrolytes, Cr, BUN, glucose, C&S
• LP required for definitive diagnosis
• Gram stain, bacterial C&S, WBC count and differential, RBC count, glucose, protein concentration
• acid-fast stain if suspect TB
• PCR for specific bacteria if available (helpful if already treated with antibiotics)
• urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions
• HSV and enterovirus PCR if suspected

*lymphocytes predominate

Management
• supportive care
  • preservation of adequate cerebral perfusion by maintaining normal BP and managing ↑ ICP
  • close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies
  • bacterial meningitis
    • if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
    • adjuvant dexamethasone BEFORE antibiotic for Hib meningitis; consider for those >6 wk with pneumococcal meningitis
    • isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
    • fluid restrict if any concern for SIADH
    • hearing test
    • report to Public Health; prophylactic antibiotics for close contacts of Hib and N. meningitidis meningitis

Signs of Meningismus
• BONK on the head
• Brudzinski’s sign
• Opisthotonos*
• Nuchal rigidity
• Kernig’s sign

*Opisthotonos: rigid spasm of the body, with the back fully arched and the heels and head bent back

</tbody>
</table>

- viral meningitis
  - mainly supportive (except for HSV)
  - acyclovir for HSV meningitis
  - report to Public Health
- prophylaxis: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see *Routine Immunization*, P3)

### Complications
- mortality: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > HIB
- acute: SIADH, subdural effusion/empyema, brain abscess, disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- chronic: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

## Mumps

### Definition
- acute, self-limited viral infection that is most commonly characterized by adenitis and swelling of the parotid glands

### Epidemiology
- incidence in Ontario has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per yr
- majority of reported cases in children between 5-10 yr of age

### Etiology
- mumps virus (RNA virus of the genus *Rubulavirus* in the *Paramyxoviridae* family)
- transmission via respiratory droplets, direct contact, fomites
- incubation period: 14-25 d
- infectivity period: 7 d pre-parotitis to 5 d post-parotitis
- upper respiratory tract → lymph nodes → salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid

### History
- non-specific prodome of fever, headache, malaise, myalgias (especially neck pain)
- usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
- parotid gland is tender and pain worsened with spicy or sour foods
- one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

### Investigations
- clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
  - may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
  - blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

### Management
- mainly supportive: analgesics, antipyretics, warm or cold packs to parotid may be soothing
- admit to hospital if serious complications (meningitis, pancreatitis)
- droplet precautions recommended until 5 d after onset of parotid swelling
- prophylaxis: routine vaccination (see *Routine Immunization*, P3)

### Complications
- common: aseptic meningitis, orchitis/oophoritis
- less common: encephalitis, pancreatitis, thyroiditis, myocarditis, arthritis, GN, ocular complications, hearing impairment
Pertussis

Definition
• prolonged respiratory illness characterized by paroxysmal coughing and inspiratory “whoop”

Epidemiology
• ~10 million children <1 yr old affected worldwide, causes up to 400,000 deaths/yr
• greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

Etiology
• *Bordetella pertussis*: Gram negative pleomorphic rod
• highly contagious; transmitted via respiratory droplets released during intense coughing
• incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

History
• prodromal catarrhal stage
  • lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or LOW-GRADE fever
• paroxysmal stage
  • lasts 4-6 wk; characterized by paroxysms of cough (“100 day cough”), sometimes followed by inspiratory whoop (“whooping cough”)
  • infants <6 mo may present with post-tussive apnea, whoop is often absent
  • onset of attacks precipitated by yawning, sneezing, eating, physical exertion
  • ± post-tussive emesis, may become cyanotic before whoop
• convalescent stage:
  • lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
  • non-infectious but cough may last up to 6 mo

Investigations
• NP specimen using aspirate or NP swab
  • gold standard: culture using special media (Regan-Lowe agar)
  • PCR to detect pertussis antigens
• blood work: CBC (lymphocytosis) and serology (antibodies against *B. pertussis*)

Management
• admit if paroxysms of cough are associated with cyanosis and/or apnea and give O₂
• supportive care
• antimicrobial therapy indicated if *B. pertussis* isolated, or symptoms present for <21 d
  • use macrolide antibiotics (azithromycin, erythromycin, or clarithromycin)
• droplet isolation until 5 d of treatment and report to Public Health
• prophylaxis
  • macrolide antibiotics for all household contacts
  • prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) (see Routine Immunization, P3)

Complications
• pressure-related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
• respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
• neurological: seizures (~3%), encephalopathy, ICH
• mortality: ~0.3%; highest risk in infants <6 mo old

Pneumonia
• see Pediatric Respirology, P88

Periorbital (Preseptal) and Orbital Cellulitis
• see Ophthalmology, OP10

Cardinal Signs of Orbital Cellulitis
• Ophthalmoplegia/diplopia
• Decreased visual acuity
• Pain with extraocular eye movement

Sexually Transmitted Infection
• see Family Medicine, FM45 and Gynecology, GY25
Sinusitis

- see Family Medicine, FM46
- complication of ≤10% of URTIs in children
- clinical diagnosis
- diagnostic imaging is NOT required to confirm diagnosis in children
  - routine CT not recommended, but consider if suspect complications of sinusitis, persistent/recurrent disease, need for surgery
- antibiotic therapy for all children (although nearly half resolve spontaneously within 4 wk)
- complications: preseptal/orbital (preseptal/orbital cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumour

Urinary Tract Infection

Definition
- infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology
- overall prevalence in infants and young children presenting with fever is 7%
- <4-6 wk old: more common in boys
- >1 yr old: females have two- to four-fold higher prevalence

Etiology
- majority (>95%) have a monomicrobial cause (~70% E. coli)
- Gram-negative bacilli: E. coli, Klebsiella, Proteus, Enterobacter, Pseudomonas
- Gram-positive cocci: S. saprophyticus, Enterococcus

Risk Factors
- non-modifiable: female gender, Caucasian, previous UTIs, family history
- modifiable: urinary tract abnormalities (VUR, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training

History
- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice if <28 d old, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal and/or flank pain

Physical Exam
- infants and young child: toxic vs non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g. hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or CVA tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT, or HTN secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations
- sterile urine specimen
  - clean catch, catheterization, or suprapubic aspiration
  - urinalysis (leukocyte esterase, nitrites, erythrocytes, hemoglobin), microscopy (bacteria and leukocytes, erythrocytes), C&S
  - diagnosis established if urinalysis suggests infection AND if ≥50,000 colony-forming units per mL of a uropathogen cultured

Management
- admit if: <2 mo old, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised, complex urologic pathology, inadequate follow-up, failure to respond to outpatient therapy
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
  - base on local antimicrobial susceptibility patterns
  - commence broad empiric therapy until results of urine C&S known, and then tailor as appropriate
  - neonates: IV ampicillin and gentamicin
  - infants and older children: oral antibiotics (based on local E.coli sensitivity) if outpatient; IV ampicillin and gentamicin if inpatient
  - duration 7-10 d
- imaging
  - renal and bladder U/S for all febrile infants (<2 yr) with UTIs looking for anatomical abnormalities, hydrenephrosis, abscess
  - VCUG not recommended after 1st febrile UTI unless U/S reveals hydrenephrosis, obstructive uropathies or other signs suggestive of high-grade VUR

Features Suggestive of Pyelonephritis
- High-grade fever
- Flank or high abdominal pain
- CVA tenderness on palpation

Bagged urine specimen not useful for ruling in UTI (high false positive rate >85%), but useful for ruling out UTI (high sensitivity)

Prophylaxis After First Febrile Urinary Tract Infection in Children? A Multicentre, Randomized Controlled, Noninferiority Trial

Study: Randomized, controlled, open-label, 2 armed, noninferiority trial.

Patients: 338 patients aged 2 mo to <7 yr who had a first episode of febrile UTI.

Intervention: No prophylaxis vs. prophylaxis.

Outcome: Recurrence rate of febrile UTI and rate of renal scarring.

Results: No significant difference in recurrence rate or in the rate of renal scarring between the prophylaxis and no prophylaxis group.
• follow-up: outpatients to return in 24-48 h if no clinical response and seek prompt medical evaluation for future febrile illnesses
• prophylaxis: generally not recommended unless higher grades of VUR

**Complications**

• long-term morbidity: focal renal scarring develops in 8% of patients; long-term significance unknown

---

**Neonatology**

**Gestational Age and Size**

**Definitions**

• classification by GA
  - preterm: <37 wk
  - near-term: 35-37 wk
  - term: 37-42 wk
  - post-term: >42 wk

• classification by birth weight
  - SGA: 2 SD < mean weight for GA or <10th percentile
  - AGA: within 2 SD of mean weight for GA
  - LGA: 2 SD > mean weight for GA or >90th percentile

**Table 26. Abnormalities of Gestational Age and Size**

**Routine Neonatal Care**

1. erythromycin ointment: applied to both eyes for prophylaxis of ophthalmia neonatorum (of questionable efficacy)
2. vitamin K IM: prophylaxis against HDNB
3. newborn screening tests in Ontario
   - in Ontario, newborn screening tests for
     - metabolic disorders (amino acid disorders, organic acid disorders, fatty acid oxidation defects, biotinidase deficiency, galactosemia)
     - blood disorders (SCD, other hemoglobinopathies)
     - endocrine disorders (CAH, congenital hypothyroidism)
     - others (CF, severe combined immunodeficiency)
     - congenital hearing loss
4. if mother Rh negative: send cord blood for blood group and direct antiglobulin test
5. if mother hepatitis B surface antigen positive: HBIG and start hepatitis B vaccine series
**Neonatal Resuscitation**

- assess Apgar score at 1 and 5 min
- if <7 at 5 min then reassess q5min, until >7
- do not wait to assign Apgar score before initiating resuscitation

### Table 27. Apgar Score

</tbody>
</table>

### Initial Resuscitation

- anticipation: know maternal history, history of pregnancy, labour, and delivery
- steps to take for all infants (before ABCs)
  - warm (radiant heater, warm towels) and dry the newborn (remove wet towels)
  - position and clear airway (“sniffing” position)
  - stimulate infant: rub lower back gently or flick soles of feet EXCEPT if meconium present (in which case tracheal suction first)
  - assess breathing and heart rate

- Airway
  - if meconium is present and
    - baby is vigorous (strong respiratory effort, good muscle tone, HR >100): no further resuscitative interventions required
    - baby is not vigorous: intubate and suction trachea while monitoring vital signs; if prolonged or unsuccessful intubation, attempt bag mask ventilation
  - if no meconium and suction required, suction mouth first and then nose

- Breathing
  - if HR <100 or apneic, apply PPV
  - PPV at rate of 40-60/min with enough pressure to see visible chest expansion and note increase in HR
  - monitor preductal SpO₂
  - if PPV not effective (no increase in HR, no chest rise, low SpO₂), incorporate corrective actions

- Circulation
  - if HR <60 after 30 s of effective ventilation, start chest compressions (“60 or less, compress”)
  - should provide 100% oxygen as soon as chest compressions are required
  - chest compressions at lower 1/3 of the sternum and 1/3 of the AP depth at a rate of 120 events per min (3 compressions:1 ventilation = 120 compressions/min:40 breaths/min)

### Table 28. Interventions Used in Neonatal Resuscitation

<table>
<thead>
<tr>
<th>Intervention</th>
<th>Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Epinephrine (adrenaline)</td>
<td>0.1-0.3 mL/kg/dose of 1:10,000 (0.01-0.03 mg/kg) IV 0.5-1 mL/kg/dose of 1:10,000 (0.05-0.1 mg/kg) endotracheally can be considered while awaiting IV access (IV preferred) Can be repeated q3-5 min prn</td>
<td>HR &lt;60 and not rising</td>
<td>Side effects: tachycardia, HTN, cardiac arrhythmias</td>
</tr>
<tr>
<td>Naloxone (Narcan®)</td>
<td>0.1 mg/kg IV/IM</td>
<td>Not recommended as part of initial resuscitation HR and oxygenation should be restored by supporting ventilation</td>
<td>Do not use for chronic opiate exposure – may cause withdrawal symptoms including HTN, irritability, seizures Action of opioid outlasts action of naloxone therefore close monitoring required after administration</td>
</tr>
<tr>
<td>Fluid Bolus (NS, whole blood, Ringer’s lactate)</td>
<td>10 mL/kg</td>
<td>May need to be repeated Avoid giving too rapidly as large volume rapid infusions can be associated with IVH</td>
<td>Evidence of hypovolemia</td>
</tr>
</tbody>
</table>
### Approach to the Depressed Newborn

- A depressed newborn lacks one or more of the following characteristics of a normal newborn:
  - Pulse > 100 bpm
  - Cries when stimulated
  - Actively moves all extremities
  - Has a good strong cry
- Approximately 10% of newborn babies require assistance with breathing after delivery.

### Diagnosis

- Vital signs
- Detailed maternal history: include prenatal care, illnesses, use of drugs, labour, previous high risk pregnancies, infections during pregnancy, current infections, duration of ruptured membranes, blood type and Rh status, amniotic fluid status, GA, meconium, Apgar scores
- Clinical findings (observe for signs of respiratory distress such as cyanosis, tachypnea, retractions, grunting, temperature instability)
- Laboratory results (CBC, ABG, blood type, glucose)
- Transillumination of chest to evaluate for pneumothorax
- CXR

### Management

- ABCs
- Intubation and suction if meconium present
- Apply tactile stimulation if no meconium
- Provide PPV if apneic or HR < 100 bpm
- Monitor SpO2 and HR (if < 60 bpm, start chest compressions)
- Provide ventilatory support and treat the underlying cause

## Common Conditions of Neonates

### Apnea

#### Definition

- "Periodic breathing": normal respiratory pattern seen in newborns in which periods of rapid respiration are alternated with pauses lasting 5-10 s
- "Apnea": absence of respiratory gas flow for > 20 s (or less if associated with bradycardia or desaturation) – 3 types
  - Central: no chest wall movement, no signs of obstruction
  - Obstructive: chest wall movement continues against obstructed upper airway, no airflow
  - Mixed: combination of central and obstructive apnea

#### Differential Diagnosis

- In term infants, apnea requires full workup as it can be associated with sepsis
Common Conditions of Neonates

• other causes
  ▪ CNS
    ▪ apnea of prematurity (<34 wk): combination of CNS immaturity and obstructive apnea; resolves by 36 wk GA; diagnosis of exclusion
    ▪ seizures
    ▪ ICH
    ▪ hypoxic injury
  ▪ infectious: sepsis, meningitis, NEC
  ▪ GI: GERD, aspiration with feeding
  ▪ metabolic: hypoglycemia, hyponatremia, hypocalcemia, inborn error of metabolism
  ▪ cardiovascular: anemia, hypovolemia, PDA, heart failure
  ▪ medications: morphine

Management
• O₂, ventilatory support, maintain normal blood gases
• tactile stimulation
• correct underlying cause
• medications: methylxanthines (caffeine) stimulate the CNS and diaphragm and are used for apnea of prematurity (not in term infants)

Bleeding Disorders in Neonates

Clinical Presentation
• oozing from the umbilical stump, excessive bleeding from peripheral venipuncture/heel stick sites/IV sites, large caput succedaneum, cephalohematomas (in absence of significant birth trauma), subgaleal hemorrhage and prolonged bleeding following circumcision

Etiology
• 4 major categories
  ▪ increased platelet destruction: maternal ITP or SLE, infection/sepsis, DIC, neonatal alloimmune thrombocytopenia, autoimmune thrombocytopenia
  ▪ decreased platelet production/function: pancytopenia, bone marrow replacement, Fanconi anemia, Trisomy 13 and 18
  ▪ metabolic: congenital thyrotoxicosis, inborn error of metabolism
  ▪ coagulation factor deficiencies (see Hematology, H31): hemophilia A/B, HDNB

NEONATAL ALLOIMMUNE THROMBOCYTOPENIA

Epidemiology
• 1 per 4,000-5,000 live births

Pathophysiology
• platelet equivalent of Rh disease of the newborn
• occurs when mother is negative for HPA and fetus is positive
• development of maternal IgG antibodies against HPA antigens on fetal platelets

Clinical Presentation
• petechiae, purpura, thrombocytopenia in otherwise healthy neonate
• severe disease can lead to intracranial bleeding

Diagnosis
• maternal and paternal platelet typing and identification of platelet alloantibodies

Treatment
• IVIg to mother prenatally starts in second trimester ± steroids ± fetal platelet transfusions
• treat neonate with IVIg
• if transfusion required should be with washed maternal platelets or donor HPA negative platelets

AUTOIMMUNE THROMBOCYTOPENIA

Pathophysiology
• caused by antiplatelet antibodies from maternal ITP or SLE
• passive transfer of antibodies across placenta

Clinical Presentation
• similar presentation to neonatal alloimmune thrombocytopenia, but thrombocytopenia usually less severe

Treatment
• steroids to mother for 10-14 d prior to delivery or IVIg to mother before delivery
• treat neonate with IVIg (usually if platelets <60,000)
• transfusion of infant with maternal/donor platelets only in severe cases, as antibodies will destroy transfused platelets
HEMORRHAGIC DISEASE OF THE NEWBORN

Pathophysiology
- caused by vitamin K deficiency
- factors II, VII, IX, X are vitamin K-dependent, therefore both PT and PTT are abnormal

Etiology and Clinical Presentation
- neonates at risk of vitamin K deficiency if: vitamin K poorly transferred across the placenta; maternal use of antiepileptics; insufficient bacterial colonization of colon at birth to synthesize vitamin K; breastfed (vitamin K intake inadequate in breastfed infants)
- neonate may present with hematomas, ICH (causing apnea or seizures), internal bleeding, hematuria, bruising, prolonged bleeding (often from mucous membranes, umbilicus, circumcision, and venipunctures)

Prevention
- vitamin K IM administration at birth to all newborns

Bronchopulmonary Dysplasia

Definition
- also known as chronic lung disease
- clinically defined as $O_2$ requirement for >28 d plus persistent need for oxygen and/or ventilatory support at 36 wk corrected GA
- damage to developing lungs with prolonged intubation/ventilation

Investigations
- CXR findings may demonstrate decreased lung volumes, areas of atelectasis, and hyperinflation

Treatment
- no good treatments
- gradual wean from ventilator, optimize nutrition
- dexamethasone may help decrease inflammation and encourage weaning, but use of dexamethasone is associated with increased risk of adverse neurodevelopmental outcomes

Prognosis
- chronic respiratory failure may lead to pulmonary HTN, poor growth, and right-sided heart failure
- patients with bronchopulmonary dysplasia may continue to have significant impairment and deterioration in lung function late into adolescence
- some lung abnormalities may persist into adulthood including airway obstruction, airway hyper-reactivity, and emphysema
- associated with increased risk of adverse neurodevelopmental outcomes

Figure 12. Approach to neonatal cyanosis
Management

• ABGs
  - elevated CO₂ suggests respiratory cause
  - hyperoxia test (to distinguish between cardiac and respiratory causes of cyanosis): get baseline PaO₂ in room air, then PaO₂ on 100% O₂ for 10-15 min
    - PaO₂ <150 mmHg: suggests cyanotic CHD or possible PPHN (see Pediatric Cardiology, P16)
    - PaO₂ >150 mmHg: suggests cyanosis likely due to respiratory or non-cardiac cause
  - CXR: look for respiratory abnormalities (respiratory tract malformations, evidence of shunting, pulmonary infiltrates) and cardiac abnormalities (cardiomegaly, abnormalities of the great vessels)

Diaphragmatic Hernia

• see General Surgery, GS64

Definition

• developmental defect of the diaphragm with herniation of abdominal organs into thorax
• associated with pulmonary hypoplasia and PPHN

Clinical Presentation

• respiratory distress, cyanosis
• scaphoid abdomen and barrel-shaped chest
• affected side dull to percussion and breath sounds absent, may hear bowel sounds instead
• heart sounds shifted to contralateral side
• asymmetric chest movements, trachea deviated away from affected side
• may present outside of neonatal period
• often associated with other anomalies (cardiovascular, CNS, chromosomal abnormalities)
• CXR: bowel loops in thorax (usually left side), displaced mediastinum

Treatment

• immediate intubation required at birth: DO NOT bag mask ventilate because air will enter stomach and further compress lungs
• place large bore orogastric tube to decompress bowel
• initial stabilization and management of pulmonary hypoplasia and PPHN, hemodynamic support and surgery when stable

Hypoglycemia

Definition

• glucose <2.6 mmol/L

Etiology

• decreased carbohydrate stores: premature, SGA, RDS, maternal HTN
• endocrine: hormonal deficiencies (GH, cortisol, epinephrine), insulin excess (infant of diabetic mother, Beckwith-Wiedemann syndrome/islet cell hyperplasia), HPA axis suppression (panhypopituitarism)
• inborn errors of metabolism: fatty acid oxidation defects, galactosemia
• miscellaneous: sepsis, hypothermia, polycythemia

Clinical Findings

• signs often non-specific and subtle: lethargy, poor feeding, irritability, tremors, apnea, cyanosis, seizures

Management

• identify and monitor infants at risk (pre-feed blood glucose checks)
• begin oral feeds as soon as possible after birth and ensure regular feeds
• if significant and/or symptomatic hypoglycemia, provide glucose IV and titrate according to blood sugar levels
• if persistent hypoglycemia or no predisposing cause, send “critical blood work” during an episode of hypoglycemia: ABG, ammonia, β-hydroxybutyrate, cortisol, free fatty acids, GH, insulin, lactate, urine dipstick for ketones

Carboxyhemoglobinemia (secondary to carbon monoxide poisoning) results in impaired binding of oxygen to hemoglobin but does not discolour the blood. Therefore it may not register on pulse oximetry and cyanosis may not be evident clinically.

Methemoglobinemia typically reads higher on pulse oximetry than the true level of oxyhemoglobin. Methemoglobin alters the absorption of red light at the two wavelengths that pulse oximetry uses to predict oxygen saturation.
**Intraventricular Hemorrhage**

**Definition**
- hemorrhage originating in the periventricular subependymal germinal matrix

**Epidemiology**
- incidence and severity inversely proportional to GA
- 50% of IVH occurs within 8 h of birth; 90% occurs by day 3

**Risk Factors**
- prematurity (<32 wk), BW <1,500 g, need for vigorous resuscitation at birth, pneumothorax, ventilated preterm infants, hemodynamic instability, RDS, coagulopathy

**Clinical Presentation**
- many infants with IVH are asymptomatic
- subtle signs: apnea, bradycardia, changes in tone or activity, altered LOC
- catastrophic presentation: bulging fontanelle, sudden drop in hematocrit, acidosis, seizures, hypotension

**Classification**
- Papile classification
- parenchymal hemorrhage may also occur in the absence of IVH
- routine head U/S screening of all preterm infants <32 wk or <1,500 g gestation throughout NICU stay
- consider MRI at term for extremely LBW infants

**Management of Acute Hemorrhage**
- supportive care to maintain blood volume and acid-base status
- avoid fluctuations in blood pressure and cerebral blood flow
- follow-up with serial imaging

**Prognosis**
- outcome depends on grade of IVH
- short-term sequelae for severe IVH: mortality, extension of bleed, posthemorrhagic hydrocephalus, posthemorrhagic infarction, cyst formation
- possible long-term major neurological sequelae: CP, cognitive deficits, motor deficits, visual and hearing impairment
- Grades I and II hemorrhages have a relatively favourable prognosis
- greatest morbidity and mortality is seen with Grade IV hemorrhage and posthemorrhagic hydrocephalus requiring ventriculoperitoneal shunt placement

**Jaundice**

**Clinical Presentation**
- jaundice is visible at serum bilirubin levels of 85-120 µmol/L; visual assessment is often misleading
- look at sclera, tip of nose in natural light
- jaundice more severe/prolonged (due to increased retention of bilirubin in the circulation) with: prematurity, acidosis, hypoalbuminemia, dehydration, hemolysis

**Hyperbilirubinemia**

- **Unconjugated**
  - **Pathologic**
    - Intrinsic
      - Membrane
        - Spherocytosis
      - Enzyme
        - G6PD deficiency
      - PK deficiency
      - Hemoglobin
        - α-thalassemia
    - Extrinsic
      - Immune
        - ABO incompatibility
      - Rh incompatibility
      - Kell, Duffy, etc.
      - Non-immune
        - Spleenomegaly
      - Seizis
        - AV malformation
  - **Physiologic**
    - Non-Hemolytic
      - Hematoma
        - cephalohematoma
      - Polycythemia
      - Sepsis
      - Hypothyroidism
      - Gilbert syndrome
      - Crigler-Najjar
  - **Always pathologic**
    - Hepatic
      - Infectious
        - Sepsis
      - Hep B, TORCH
    - Metabolic
      - Galactosemia
      - Tyrosinemia
      - α-1-antitrypsin deficiency
      - Hypothyroidism
    - CF
    - Drugs
    - TPN
    - Idiopathic neonatal hepatitis

**Figure 13. Approach to neonatal hyperbilirubinemia**
PHYSIOLOGIC JAUNDICE

Epidemiology
• term infants: onset 3-4 d of life, resolution by 10 d of life
• premature infants: higher peak and longer duration

Pathophysiology
• increased hematocrit and decreased RBC lifespan
• immature glucuronyl transferase enzyme system (slow conjugation of bilirubin)
• increased enterohepatic circulation

Breastfeeding Jaundice
• common; due to a lack of milk production → dehydration → exaggerated physiologic jaundice

Breast Milk Jaundice
• 1 per 200 breastfed infants
• glucuronyl transferase inhibitor found in breast milk
• onset 7 d of life, peak at 2-3 wk of life, usually resolved by 6 wk

PATHOLOGIC JAUNDICE
• all cases of conjugated hyperbilirubinemia; some cases of unconjugated hyperbilirubinemia are pathologic

Investigations
• unconjugated hyperbilirubinemia
  ▪ hemolytic workup: CBC, reticulocyte count, blood group (mother and infant), peripheral
    blood smear, Coombs test
  ▪ if baby is unwell or has fever: septic workup (CBC and differential, blood and urine cultures
    ± LP, CXR)
  ▪ other: G6PD screen (especially in males), TSH
• conjugated hyperbilirubinemia must be investigated without delay
  ▪ consider liver enzymes (AST, ALT), coagulation studies (PT, PTT), serum albumin, ammonia, TSH, TORCH screen, septic workup, galactosemia screen (erythrocyte galactose-1-phosphate uridyltransferase levels), metabolic screen, abdominal U/S, HIDA scan, sweat
  chloride

TREATMENT OF UNCONJUGATED HYPERBILIRUBINEMIA
• to prevent kernicterus
• breastfeeding does not usually need to be discontinued, ensure adequate feeds and hydration
• lactation consultant support, mother to pump after feeds
• treat underlying causes (e.g. sepsis)
• phototherapy (blue-green wavelength, not UV light)
  ▪ insoluble unconjugated bilirubin is converted to excretable form via photoisomerization
  ▪ serum bilirubin should be monitored during and immediately after therapy (risk of rebound
    because photoisomerization reversible when phototherapy discontinued)
- contraindicated in conjugated hyperbilirubinemia: results in “bronzed” baby
- side effects: skin rash, diarrhea, eye damage (eye shield used routinely for prevention), dehydration
- use published guidelines and nomogram for initiation of phototherapy
- exchange transfusion
  - indications: high bilirubin levels as per published graphs based on age, weeks gestation
  - most commonly performed for hemolytic disease and G6PD deficiency
  - use of IVIg in case of severe hyperbilirubinemia (DAT+) becoming evidence-based practice

KERNICTERUS

Etiology
- unconjugated bilirubin concentrations exceed albumin binding capacity and bilirubin is deposited in the brain resulting in permanent damage (typically basal ganglia or brainstem)
- incidence increases as serum bilirubin levels increase above 340 µmol/L
- can occur at lower levels in presence of sepsis, meningitis, hemolysis, hypoxia, acidosis, hypothermia, hypoglycemia, and prematurity

Clinical Presentation
- up to 15% of infants have no obvious neurologic symptoms
- early stage: lethargy, hypotonia, poor feeding, emesis (bilirubin encephalopathy)
- mid stage: hypertonia, high pitched cry, opisthotonic posturing (back arching), bulging fontanelle, seizures, pulmonary hemorrhage
- late stage (first year and beyond)
  - hypotonia, delayed motor skills, extrapyramidal abnormalities (choreoathetoid CP), gaze palsy, mitral regurgitation, sensorineural hearing loss

Prevention
- exchange transfusion, IVIg if indicated

BILIARY ATRESIA

Definition
- atresia of the extrahepatic bile ducts which leads to cholestasis and increased conjugated bilirubin after the first week of life
- progressive obliterative cholangiopathy

Epidemiology
- incidence: 1:10,000-15,000 live births
- associated anomalies in 10-35% of cases: situs inversus, congenital heart defects, polysplenia

Clinical Presentation
- dark urine, pale stool, jaundice (persisting for >2 wk), abdominal distension, hepatomegaly

Diagnosis
- conjugated hyperbilirubinemia, abdominal U/S
- HIDA scan (may be bypassed in favour of biopsy if timing of diagnosis is critical)
- liver biopsy

Treatment
- surgical drainage procedure
- hepatopancreatobiliary (Kasai procedure; most successful if <8 wk of age)
- two-thirds will eventually require liver transplantation
- vitamins A, D, E, and K; diet should be enriched with medium-chain triglycerides to ensure adequate fat ingestion

Necrotizing Enterocolitis

Definition
- intestinal inflammation associated with focal or diffuse ulceration and necrosis
- primarily affecting terminal ileum and colon

Epidemiology
- affects 1-5% of preterm newborns admitted to NICU
Pathophysiology
- postulated mechanism of bowel ischemia: mucosal damage and enteral feeding → bacterial growth → bowel necrosis/gangrene/perforation

Risk Factors
- prematurity (immature defenses)
- asphyxia, shock (poor bowel perfusion)
- hyperosmolar feeds
- enteral feeding with formula (breast milk can be protective)
- sepsis

Clinical Presentation
- usually presents at 2-3 wk of age
- distended abdomen
- increased amount of gastric aspirate/vomitus with bile staining
- frank or occult blood in stool
- feeding intolerance
- diminished bowel sounds
- signs of bowel perforation (sepsis, shock, peritonitis, DIC)

Investigations
- AXR: pneumonitis intestinalis (intramural air is a hallmark of NEC), free air, fixed loops, ileus, thickened bowel wall, portal venous gas
- CBC, ABG, lactate, blood culture, electrolytes
- high or low WBC, low platelets, hyponatremia, acidosis, hypoxia, hypercapnea

Treatment
- NPO (7-10 d), vigorous IV fluid resuscitation, decompression with NG tube, supportive therapy
- TPN
- antibiotics (usually ampicillin, gentamicin ± metronidazole if risk of perforation x 7-10 d)
- serial AXRs detect early perforation (40% mortality in perforated NEC)
- peritoneal drain/surgery if perforation
- surgical resection of necrotic bowel and surgery for complications (e.g. perforation, strictures)

Persistent Pulmonary Hypertension of the Newborn

Epidemiology
- incidence 1.9/1,000 live births

Clinical Presentation
- usually presents within 12 h of birth with severe hypoxemia/cyanosis; may have only mild respiratory distress

Pathophysiology
- persistence of fetal circulation as a result of persistent elevation of pulmonary vascular resistance
- R → L shunt through PDA, foramen ovale → decreased pulmonary blood flow and hypoxemia → further pulmonary vasoconstriction

Risk Factors
- secondary PPHN: asphyxia, MAS, RDS, sepsis, pneumonia, structural abnormalities (e.g. diaphragmatic hernia, pulmonary hypoplasia)
- primary PPHN occurs in absence of risk factors
- more common in term or post-term infants

Investigations
- measure pre- and post-ductal oxygen levels
- hyperoxia test to exclude CHD
- ECG (RV strain)
- Echo reveals increased pulmonary arterial pressure and a R → L shunt across PDA and patent foramen ovale; also used to rule out other cardiac defects

Treatment
- maintain good oxygenation (SaO₂ >95%) in at-risk infants
- O₂, given early and tapered slowly, minimize stress and metabolic demands, maintain normal blood gases, circulatory support
- mechanical ventilation, high frequency oscillation in a sedated muscle-relaxed infant
- nitric oxide, surfactant
- extracorporeal membrane oxygenation used in some centres when other therapy fails
Respiratory Distress in the Newborn

Clinical Presentation
- tachypnea: RR >60/min; tachycardia: HR >160/min
- grunting, substernal/intercostal indrawing, nasal flaring
- duskiness, central cyanosis
- decreased air entry, crackles on auscultation

Differential Diagnosis of Respiratory Distress
- pulmonary: RDS, TTN, MAS, pleural effusion, pneumothorax, congenital lung malformations
- infectious: sepsis, pneumonia
- cardiac: CHD (cyanotic, acyanotic), PPHN
- hematologic: blood loss, polycythemia
- anatomic: TEF, congenital diaphragmatic hernia, mucous or meconium plug, upper airway obstruction (see Otolaryngology, OT44)
- metabolic: hypoglycemia, inborn errors of metabolism
- neurologic: CNS damage (trauma, hemorrhage), drug withdrawal syndromes

Investigations
- CXR, ABG (or venous blood gas from umbilical venous line)
- CBC, blood cultures, blood glucose
- Echo, ECG if indicated

Table 32. Distinguishing Features of RDS, TTN, MAS

PNEUMONIA
- see Pediatric Respirology, P88
- consider in infants with prolonged or premature rupture of membranes, maternal fever, or if mother is GBS positive
- suspect if infant exhibits respiratory distress, temperature instability, or WBC is low, elevated, or left-shifted
- symptoms may be non-specific
- CXR: hazy lung and/or distinct infiltrates (may be difficult to differentiate from RDS)

Retinopathy of Prematurity
- see Ophthalmology, OP41

Sepsis in the Neonate

</tr>
<tr>
<td>Congenital Dermal Melanocytosis ('Mongolian Spots')</td>
<td>Slate gray macules over lower back and buttocks (may look like bruises); common in dark skinned infants</td>
</tr>
<tr>
<td>Capillary Hemangioma</td>
<td>Raised red lesion, which increases in size after birth and involutes; 50% resolved by 5 yr, 90% by 9 yr</td>
</tr>
<tr>
<td>Erythema Toxica</td>
<td>Yellow-white papules surrounded by erythema, eosinophils within the lesions; common rash, resolves by 2 wk</td>
</tr>
<tr>
<td>Milia</td>
<td>Lesions 1-2 mm firm white pearly papules on nasal bridge, cheeks, and palate; self-resolving</td>
</tr>
<tr>
<td>Pustular Melanosis</td>
<td>Brown macular base with pustules, seen more commonly in African American infants; may be present at birth</td>
</tr>
<tr>
<td>Nevus Simplex (Salmon Patch)</td>
<td>Transient macular vascular malformation of the eyelids and/or neck (&quot;Angel Kiss&quot; or &quot;Stork Bite&quot;); most lesions disappear by 1 yr of life</td>
</tr>
<tr>
<td>Neonatal Acne</td>
<td>Inflammatory papules and pustules mainly on face; self-resolving</td>
</tr>
</tbody>
</table>

### Fluids and Electrolytes

#### Approach to Infant/Child with Dehydration

**Etiology**
- decreased intake: poor oral intake during acute illness, breastfeeding difficulties, eating disorders
- increased losses: common sites include GI tract (diarrhea, vomiting, bleeding), skin/mucous membranes (fever, burns, hemorrhage, stomatitis), urine (osmotic diuresis [e.g. hyperglycemia, DKA], diuretic therapy, DI, post-obstructive/post ATN recovery diuresis), and respiratory tract (tachypnea, bronchiolitis, pneumonia)

**Management**
- if suspect dehydration based on history (acute illness, decreased number of wet diapers, lethargy, changes in mental status, increased thirst, etc.), you must:
  1. Determine degree of extracellular volume contraction

**Table 35. Assessment of Degree of Extracellular Volume Contraction Based on Physical Exam**

<table>
<thead>
<tr>

</tbody>
</table>

• for moderate and severe dehydration, initial investigations should include urinalysis and blood work examining electrolyte (Na⁺, K⁺, Cl⁻), glucose, and acid-base (blood pH, pCO₂, HCO₃⁻) disturbances, and impaired renal function (creatinine, BUN)

3) Determine if the child requires PO or IV rehydration

• dehydrated child must receive adequate fluid management, including replacement of ongoing losses and maintenance fluids

• ORT indication: mild to moderate dehydration caused by diarrhea
  ■ advantages: ↓ cost, no IV needed, no increase in incidence of iatrogenic hyper/hyponatremia, parental involvement in therapy

• IV rehydration indications: indications for IV rehydration therapy: severe dehydration requiring close monitoring and frequent assessment of electrolytes, inability to tolerate ORT (e.g. vomiting, alteration in mental status, ileus, monosaccharide malabsorption, etc.), inability to provide ORT, failure of ORT in providing adequate rehydration (e.g. persistent diarrhea or vomiting)

4) Return the child to a normal volume and electrolyte status by replacing current deficits and ongoing losses

5) Provide the appropriate fluid and electrolyte maintenance daily requirements

Table 37. Maintenance Fluid Requirements

<table>
<thead>
<tr>
<th>Body Weight</th>
<th>100:50:20 Rule (24 h maintenance fluids)</th>
<th>4:2:1 Rule (hourly rate of maintenance fluids)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-10 kg</td>

<td>50 cc/kg/d</td>
<td>2 cc/kg/h</td>
</tr>
<tr>
<td>&gt;20 kg</td>
<td>20 cc/kg/d</td>
<td>1 cc/kg/h</td>
</tr>
</tbody>
</table>

• types of fluids used: NS, RL, half NS (0.45% NaCl), 0.2% NS (for neonates only), D5W, and D10W (for neonates only); add potassium chloride if hypokalemic

• in children, all maintenance fluids should have a dextrose component due to their higher risk of hypoglycemia, especially if they are NPO

• common IV fluid combinations used in pediatrics
  ■ first month of life: D5W/0.45 2 NS + KCl 20 mEq/L (only add KCl if voiding well)
  ■ children: D5W/NS + KCl 20 mEq/L or D5W/0.45 NS + KCl 20 mEq/L
  ■ NS: as bolus to restore circulation in dehydrated children (remains almost entirely distributed in intravascular space)
• most important thing to remember when correcting Na aberrations due to fluid deficits
  ▪ risk of cerebral edema with rapid rehydration with hypotonic or isotonic solutions (i.e. NS), therefore replace fluid slowly with close monitoring; aim to adjust (increase or decrease) plasma [Na+] by no more than 12 mmol/L/d
  ▪ management depends on etiology, severity of symptoms, and timing (acute vs. chronic)

6) Continue to monitor fluid and electrolyte status
• accurate monitoring of daily fluid intake (PO and IV) and ongoing losses (urine output, diarrhea, emesis, drains)
• if child receiving >50% of maintenance fluids through IV, serum electrolyte values should be monitored daily and therapy adjusted accordingly
• avoid iatrogenic hyper/hyponatremia, keep the possibility of SIADH in mind

Nephrology

Common Pediatric Renal Diseases

Table 38. Common Manifestations of Renal Disease

</tr>
</tbody>
</table>

Hemolytic Uremic Syndrome

Definition
• simultaneous occurrence of the triad of 1) non-immune microangiopathic hemolytic anemia, 2) thrombocytopenia, and 3) acute renal injury

Epidemiology
• annual incidence of 1-2 per 100,000 in Canada
• most common cause of acute renal failure in children

Etiology
• diarrhea positive HUS: 90% of pediatric HUS from E. coli O157:H7, shiga toxin, or verotoxin
• diarrhea negative HUS: other bacteria, viruses, drugs, familial/genetic

Pathophysiology
• toxin binds, invades, and destroys colonic epithelial cells, causing bloody diarrhea
• toxin enters the systemic circulation, attaches to, and injures endothelial cells (especially in kidney), causing a release of endothelial products (e.g. von Willebrand factor, platelet aggregating factor)
• platelet/fibrin thrombi form in multiple organ systems (e.g. kidney, pancreas, brain, etc.) resulting in thrombocytopenia
• RBCs are forced through occluded vessels, resulting in fragmented RBCs (schistocytes) that are removed by the reticuloendothelial system (hemolytic anemia)
History and Physical Exam

- history: initial presentation of abdominal pain and diarrhea, followed by bloody diarrhea; within 5-7 days begins to show signs of anemia, thrombocytopenia, and renal insufficiency
- physical exam: pallor, jaundice (hemolysis), edema, petechiae, HTN

Investigations

- CBC (anemia, thrombocytopenia), blood smear (schistocytes), electrolytes, renal function, urinalysis (microscopic hematuria), stool cultures, and verotoxin/shigella toxin assay

Management

- mainly supportive: nutrition, hydration, ventilation (if necessary), blood transfusion for symptomatic anemia
- monitor electrolytes and renal function: dialysis if electrolyte abnormality (hyperkalemia) cannot be corrected, fluid overload, or uremia
- steroids are not helpful
- antibiotics are contraindicated because death of bacteria leads to increased toxin release and worse clinical course

Prognosis

- <5% mortality, 5-25% long-term renal damage (HTN, proteinuria, decreased renal function)

Nephritic Syndrome

Definition

- acute or chronic syndrome affecting the kidney, characterized by glomerular injury and inflammation, and defined by hematuria (>5 RBCs per high-powered microscope field) and the presence of dysmorphic RBCs and RBC casts on urinalysis
- often accompanied by at least one of proteinuria (<50 mg/kg/d), edema, HTN, azotemia, and oliguria

Epidemiology

- highest incidence in children aged 5-15 yr old

Etiology

- humoral immune response to a variety of etiologic agents → immunoglobulin deposition → complement activation, leukocyte recruitment, release of growth factors/cytokines → glomerular inflammation and injury → porous podocytes → hematuria + RBC casts ± proteinuria
- HTN secondary to fluid retention and increased renin secretion by ischemic kidneys

Table 39. Major Causes of Nephritic Syndrome

<table>
<thead>
<tr>
<th>Decreased C3</th>
<th>Normal C3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary (idiopathic)</td>
<td></td>
</tr>
<tr>
<td>Post-infectious GN (most common cause of acute GN in pediatrics)</td>
<td>IgA nephropathy</td>
</tr>
<tr>

</tr>
<tr>
<td>Abscess or shunt nephritis</td>
<td>Granulomatosis with polyangiitis</td>
</tr>
<tr>
<td>Cryoglobulinemia</td>
<td>Goodpasture’s syndrome</td>
</tr>
</tbody>
</table>

Risk Factors

- see Major Causes of Nephritic Syndrome, above

History and Physical Exam

- often asymptomatic; some overlap in clinical findings for nephritic and nephrotic syndrome
- gross hematuria, mild-moderate edema, oliguria, HTN
- signs and symptoms suggestive of underlying systemic causes (e.g. fever, arthralgias, rash, dyspnea, pulmonary hemorrhage)

Investigations

- urine
  - dipstick (hematuria, 0 to 2+ proteinuria) and microscopy (>5 RBCs per high-powered microscope field, acanthocytes, RBC casts)
  - first morning urine protein/creatinine ratio (<200 mg/mmol)
blood work
- impaired renal function (↑ Cr and BUN) resulting in ↓ pH and electrolyte abnormalities (hyperkalemia, hyperphosphatemia, hypocalcemia)
- mild anemia on CBC (secondary to hematuria)
- hypoalbuminemia (secondary to proteinuria)
- appropriate investigations to determine etiology: C3/C4 levels, serologic testing for recent streptococcal infection (ASOT, anti-hyaluronidase, anti-streptokinase, anti-NAD, anti-DNase B), ANA, anti-DNA antibodies, ANCA, serum IgA levels, anti-GBM antibodies
- renal biopsy should be considered only in the presence of acute renal failure, no evidence of streptococcal infection, normal C3/C4

Management
- treat underlying cause
- symptomatic
  - renal insufficiency: supportive (dialysis if necessary), proper hydration
  - HTN: salt and fluid restriction (but not at expense of renal function), ACE inhibitors or ARBs for chronic persistent HTN (not acute cases because ACE inhibitors or ARBs may decrease GFR further)
  - edema: salt and fluid restriction, possibly diuretics (avoid if significant intravascular depletion)
  - corticosteroids if indicated: IgA nephropathy, lupus nephritis, etc.

Prognosis
- dependent on underlying etiology
- complications include HTN, heart failure, pulmonary edema, chronic kidney injury (requiring renal transplant)

Nephrotic Syndrome

Definition
- clinical syndrome affecting the kidney, characterized by significant proteinuria, peripheral edema, hypoalbuminemia, and hyperlipidemia

Epidemiology
- highest incidence in children 2-6 yr old, M>F

Etiology
- primary (idiopathic): nephrotic syndrome in the absence of systemic disease (most common cause in pediatrics)
  - glomerular inflammation ABSENT on renal biopsy: MCD (85%), focal segmental glomerular sclerosis
  - glomerular inflammation PRESENT on renal biopsy: membranoproliferative GN, IgA nephropathy
- secondary: nephrotic syndrome associated with systemic disease or due to another process causing glomerular injury (<10% in pediatrics)
  - autoimmune: SLE, DM, rheumatoid arthritis
  - genetic: sickle cell disease, Alport syndrome
  - infections: hepatitis B/C, post-streptococcal, infective endocarditis, HUS, HIV
  - malignancies: leukemia, lymphoma
  - medications: captopril, penicillamine, NSAIDs, antiepileptics
  - vasculitides: HSP, granulomatosis with polyangiitis
- congenital: congenital nephropathy of the Finnish type, Denys-Drash syndrome, etc.

Risk Factors
- family history, certain systemic illnesses and medications (as per Etiology)

History and Physical Exam
- non-specific symptoms such as irritability, malaise, fatigue, anorexia, or diarrhea
- edema
  - often first sign; detectable when fluid retention exceeds 3-5% of body weight
  - starts periorbital and often pretilal → edematous areas are white, soft, and pitting
  - gravity dependent: periorbital edema ↓ and pretilial edema ↑ over the day
  - anasarca may develop (i.e. marked periorbital and peripheral edema, ascites, pleural effusions, scrotal/labial edema)
  - decrease in effective circulating volume (e.g. tachycardia, HTN, oliguria, etc.)
- foamy urine is a possible sign of proteinuria
Investigations
- urine
  - urine dipstick (3 to 4+ proteinuria, microscopic hematuria) and microscopy (oval fat bodies, hyaline casts)
  - first morning urine protein/creatinine ratio (>200 mg/mmol)
- blood work
  - diagnostic: hypoalbuminemia (<25 g/L), hyperlipidemia/hypercholesterolemia (total cholesterol >5 mmol/L)
  - secondary: electrolytes (hypocalcemia, hyperkalemia, hyponatremia), renal function (↑ BUN and Cr), coagulation profile (↓ PTT)
  - appropriate investigations to rule out secondary causes: CBC, blood smear, C3/C4, ANA, hepatitis B/C titres, ASOT, HIV serology, etc.
- consider renal biopsy if: HTN, gross hematuria, ↓ renal function, low serum C3/C4, no response to steroids after 4 wk of therapy, frequent relapses (>2 in 6 mo), presentation before first year of life (high likelihood of congenital nephrotic syndrome), presentation ≥12 yr (rule out more serious renal pathology than MCD)

Management
- MCD: oral prednisone 2 mg/kg/d (or equivalent) for up to 12 wk → varicella status should be known before starting
- consider cytotoxic agents, immunomodulators, or high-dose pulse corticosteroid if steroid resistant
- symptomatic
  - edema: salt and fluid restriction, possibly diuretic (avoid if significant intravascular depletion); furosemide + albumin for anasarca
  - hyperlipidemia: generally resolves with remission; limit dietary fat intake; consider statin therapy if persistently nephrotic
  - hypoaalbuminemia: IV albumin and furosemide not routinely given; consider if refractory edema
  - abnormal BP: control BP; fluid resuscitation if severe intravascular depletion; ACE inhibitors or ARBs for persistent HTN
- diet: no added salt; monitor caloric intake and supplement with Ca²⁺ and Vit D if on corticosteroids
- daily weights and BP to assess therapeutic progress
- secondary infections: treat with appropriate antimicrobials; antibiotic prophylaxis not recommended; pneumococcal vaccine at diagnosis and varicella vaccine after remission; varicella Ig + acyclovir if exposed while on corticosteroids
- secondary hypercoagulability: mobilize, avoid hemoconcentration due to hypovolemia, prompt sepsis treatment; heparin if thrombi occur

Prognosis
- generally good: 80% of children responsive to corticosteroids
- up to 2/3 experience relapse, often multiple times; sustained remission with normal kidney function usually by adolescence
- complications: ↑ risk of infections (spontaneous peritonitis, cellulitis, sepsis); hypercoagulability due to decreased intravascular volume and antithrombin III depletion (PE, renal vein thrombosis); intravascular volume depletion, leading to hypotension, shock, renal failure; side effects of drugs

Hypertension in Childhood

Definition
- HTN: sBP and/or dBP ≥95th percentile for sex, age, and height on ≥3 occasions
- pre-HTN: sBP and/or dBP ≥90th percentile but <95th percentile OR BP ≥120/80 irrespective of age, gender, and height

</tbody>
</table>

Epidemiology
• prevalence: 3-5% for HTN, 7-10% for pre-HTN; M>F
• increasing prevalence of pre-HTN over the last 25+ years

Etiology
• primary HTN
  • diagnosis of exclusion
  • most common in older children (≥10 yr), especially if positive family history, overweight, and only mild HTN
  • responsible for ~90% of cases of HTN in adolescents, rarely in young children
• secondary HTN
  • identifiable cause of HTN (most likely etiology depends on age)
  • responsible for majority of childhood HTN
• always consider white coat HTN for all ages

<table>
<thead>

</table>

*Risk Factors
• primary HTN: male gender, positive family history, obesity, obstructive sleep apnea, African American, prematurity/LBW
• secondary HTN: history of renal disease, abdominal trauma, family history of autoimmune diseases, umbilical artery catheterization

History
• often asymptomatic, but can include FTT, fatigue, epistaxis
• symptoms of hypertensive emergency
  • neurologic: headache, seizures, local complaints, change in mental status, visual disturbances
  • cardiovascular: symptoms of MI or heart failure (chest pain, palpitations, cough, SOB)
• symptoms of secondary HTN: guided by etiology; ask about medications and recreational drugs (current and past)

Physical Exam
• BP measurement (make sure correct cuff size is used), plot on growth chart, BMI
• look for signs of hypertensive emergency (e.g. full neurologic exam, ophthalmoscopy, precordial exam, peripheral pulses, perfusion status)
• look for signs of secondary HTN

Investigations
• laboratory
  • urine dipstick for hematuria and/or proteinuria (renal disease), urine catecholamines (pheochromocytoma, neuroblastoma)
  • blood work: renal function tests (electrolytes, Cr, BUN), consider renin and aldosterone levels (RAS, Conn's syndrome, Wilms' tumour)
  • other specific hormones if indicated on history and physical
  • imaging: Echo (coarctation, heart function), abdominal U/S (RAS, abdominal mass), renal radionucleide imaging (renal scarring)
  • other: ocular exam

Management
• treat underlying cause
• non-pharmacologic: modify concurrent cardiovascular risk factors (weight reduction, exercise, salt restriction, smoking cessation)
• pharmacologic: gradual lowering of BP using thiazide diuretics; no antihypertensives have been formally studied in children; if hypertensive emergencies use hydralazine, labetalol, sodium nitroprusside
• management of end-organ damage (e.g. retinopathy, LVH)
• consider referral to specialist
Prognosis
• end-organ damage (similar to adults) including LVH, CHF, cerebrovascular insults, renal disease, retinopathy

Neurology

Seizure Disorders

Differential Diagnosis of Seizures in Children
• benign febrile seizure
• CNS: infection, tumour, HIE, trauma, hemorrhage
• metabolic: hypoglycemia, hypocalcemia, hyponatremia
• idiopathic epilepsy and epileptic syndromes
• others: neurocutaneous syndromes, AVM, drug ingestions/withdrawal
• seizure mimics

Investigations
• lab tests: CBC, electrolytes, calcium, magnesium, glucose
• toxicology screen if indicated
• EEG
• CT/MRI, if indicated (focal neurological deficit or has not returned to baseline several hours after seizure)
• consider LP if first-time non-febrile seizure (not indicated for determining recurrence risk of benign febrile seizures or to determine seizure type or epileptic syndrome)

CHILDHOOD EPILEPTIC SYNDROMES

Infantile Spasms
• brief, repeated symmetric contractions of neck, trunk, extremities (flexion and extension) lasting 10-30 s
• occur in clusters; often associated with developmental delay; onset 4-8 mo
• 20% unknown etiology (usually good response to treatment); 80% due to metabolic or developmental abnormalities, encephalopathies, or are associated with neurocutaneous syndromes (usually poor response to treatment)
• can develop into West syndrome (infantile spasms, psychomotor developmental arrest, and hyperarrhythmia) or Lennox-Gastaut (see below)
• typical EEG: hyperarrhythmia (high voltage slow waves, spikes and polyspikes, background disorganization)
• management: ACTH, vigabatrin, benzodiazepines

Lennox-Gastaut
• characterized by triad of 1) multiple seizure types, 2) diffuse cognitive dysfunction, and 3) slow generalized spike and slow wave EEG
• onset commonly 3-5 yr of age
• seen with underlying encephalopathy and brain malformations
• management: valproic acid, benzodiazepines, and ketogenic diet; however, response often poor

Juvenile Myoclonic Epilepsy (Janz Syndrome)
• myoclonus particularly in morning; frequently presents as generalized tonic-clonic seizures
• adolescent onset (12-16 yr of age); autosomal dominant with variable penetrance
• typical EEG: 3.5-6 Hz irregular spike and wave, increased with photic stimulation
• management: lifelong treatment (valproic acid); excellent prognosis

Childhood Absence Epilepsy
• multiple daily absence seizures lasting <30 s without post-ictal state that may resolve spontaneously or become generalized in adolescence
• peak age of onset 6-7 yr, F>M, strong genetic predisposition
• typical EEG: 3 Hz spike and wave
• management: valproic acid or ethosuximide

Heart problems, such as long QT syndrome and hypertrophic cardiomyopathy, are often misdiagnosed as epilepsy. Include cardiac causes of syncope in your differential diagnosis, particularly when the episodes occur during physical activity.

Seizure Mimics
• Benign paroxysmal vertigo
• Breath holding
• Hypoglycemia
• Narcolepsy
• Night terror
• Pseudoseizure
• Syncope
• TIA
• Tic
Benign Focal Epilepsy of Childhood with Rolandic/Centrotemporal Spikes

- focal motor seizures involving tongue, mouth, face, upper extremity usually occurring in sleep-wake transition states; remains conscious, but aphasic post-ictally
- onset peaks at 5-10 yr of age; 16% of all non-febrile seizures; remits spontaneously in adolescence without sequelae
- typical EEG: repetitive spikes in centrotemporal area with normal background
- management: frequent seizures controlled by carbamazepine, no medication if infrequent seizures

General Approach to Treatment

- education for patient and parents including education and precautions in daily life (e.g. buddy system, showers instead of baths)
- medication
  - initiate: treatment with drug appropriate to seizure type; often if >2 unprovoked afebrile seizures within 6-12 mo
  - optimize: start with one drug and increase dosage until seizures controlled
  - if no effect, switch over to another before adding a second antiepileptic drug
  - continue antiepileptic drug therapy until patient free of seizures for >2 yr, then wean over 4-6 mo
- ketogenic diet (high fat diet): used in patients who do not respond to polytherapy or who do not wish to take medication (valproic acid contraindicated in conjunction with ketogenic diet because may increase hepatotoxicity)
- legal obligation to report to Ministry of Transportation if patient wishes to drive

Generalized and Partial Seizures

- see Neurology, N18

Febrile Seizures

Epidemiology

- most common cause of seizure in children (3-5% of children)
- M>F; age 6 mo-6 yr

Clinical Presentation

- often with associated illness or fever and family history
- no evidence of CNS infection/inflammation before or after seizure; no history of non-febrile seizures

Table 42. Comparison of Typical and Atypical Febrile Seizures

<table>
<thead>
<tr>

<tr>
<td>• Generalized tonic-clonic</td>
<td>• Focal onset or focal features during seizure</td>
</tr>
<tr>
<td>• No recurrence in 24 h period</td>
<td>• Recurrent seizures (&gt;1 in 24 h period)</td>
</tr>
<tr>
<td>• No neurological impairment or developmental delay before or after seizure</td>
<td>• Previous neurological impairment or neurological deficit after seizure</td>
</tr>
</tbody>
</table>

Workup

- history: determine focus of fever, description of seizure, medications, trauma history, development, family history
- physical exam: LOC, signs of meningitis, neurological exam, head circumference, focus of infection
- septic workup including LP if suspecting meningitis (strongly consider if child <12 mo; consider if child is 12-18 mo; only if meningeal signs present if child >18 mo)
- if typical febrile seizure, investigations only for determining focus of fever
- EEG/CT/MRI brain not warranted unless atypical febrile seizure or abnormal neurologic findings

Management

- counsel and reassure patient and parents
  - febrile seizures do not cause brain damage
  - very small risk of developing epilepsy; 9% in child with multiple risk factors; 2% in child with typical febrile seizures compared to 1% in general population
  - 33% chance of recurrence (mostly within 1 yr of first seizure and in children <1 yr old)
  - antipyretics and fluids for comfort (though neither prevent seizure)
• prophylaxis with antiepileptic drugs not recommended
• if high risk for recurrent or prolonged seizures, have rectal or sublingual lorazepam at home
• treat underlying cause of fever

### Recurrent Headache

- see Neurology, N45

### Differential Diagnosis

- primary headache: tension, migraine, cluster
- secondary headache: see Neurology, N45

### General Assessment

- if unremarkable history and neurological and general physical exam is negative, most likely diagnosis is migraine or tension headache
- CT or MRI if history or physical reveals red flags
- inquire about level of disability, academic performance, after-school activities

### Hypotonia

- decreased resistance to passive movements – “floppy baby”

### Differential Diagnosis

- central: chromosomal (DS, Prader-Willi, Fragile X syndrome), metabolic (hypoglycemia, kernicterus), perinatal problems (asphyxia, ICH), endocrine (hypothyroidism, hypopituitarism), systemic illness (TORCH infection, sepsis, dehydration), CNS malformations, dysmorphic syndromes
- peripheral: motor neuron (spinal muscular atrophy, polio), peripheral nerve (Charcot-Marie-Tooth syndrome) neuromuscular junction (myasthenia gravis), muscle fibre (mitochondrial myopathy, muscular dystrophy, myotonic dystrophy)

### History and Physical Exam

- proper assessment of tone requires accurate determination of GA
- differentiate between UMN and LMN lesion: spontaneous posture (spontaneous movement, movement against gravity, frog-leg position); muscle weakness; joint mobility (hyperextensibility); muscle bulk; presence of fasciculations
- postural maneuvers
  - traction response: pull to sit, look for flexion of arms to counteract traction and head lag
  - axillary suspension: suspend infant by holding at axilla and lifting; hypotonic babies will slip through grasp because of low shoulder girdle tone
  - ventral suspension: infant is prone and supported under the abdomen by one hand; infant should be able to hold up extremities; inverted “U” posturing demonstrates hypotonia
- dysmorphic features, cognitive ability, reflexes, strength

### Investigations

- rule out systemic disorders (e.g. electrolytes, ABG, blood glucose, CK, and serum/urine investigations for multiple etiologies including mitochondrial causes)
- neuroimaging: MRI/MRA when indicated
- EMG, muscle biopsy/NCS
- chromosome analysis, genetic testing, metabolic testing, neuromuscular testing

### Treatment

- depends on etiology: some treatments available for specific diagnosis
- counsel parents on prognosis and genetic implications
- refer patients for specialized care, refer for rehabilitation, OT, PT, assess feeding ability

### Cerebral Palsy

#### Definition

- a symptom complex, not a disease
- non-progressive central motor impairment syndrome due to insult to or anomaly of the immature CNS
- incidence: 1.5-2.5/1,000 live births (industrialized nations)
- life expectancy is dependent on the degree of mobility and intellectual impairment, not on severity of CNS lesion
Etiology
• often obscure, no definite etiology identified in 1/3 of cases
• 10% related to intrapartum asphyxia; 10% due to postnatal insult (infections, asphyxia, prematurity with IVH and trauma)
• association with LBW babies

Clinical Presentation
• general signs: delay in motor milestones, developmental delay, learning disabilities, visual/hearing impairment, seizures, microcephaly, uncoordinated swallow (aspiration)

Investigations
• may include metabolic screen, chromosome studies, serology, neuroimaging (MRI), EMG, EEG (if seizures), ophthalmology assessment, audiology assessment

Treatment
• maximize potential through multidisciplinary services such as primary care physician, OT, PT, SLP, school supports, etc.
• orthopedic management (e.g. dislocations, contractures, rhizotomy)
• management of symptoms: spasticity (baclofen, Botox®), constipation (stool softeners)

Neurocutaneous Syndromes
• characterized by tendency to form tumours of the CNS, PNS, viscera, and skin

NEUROFIBROMATOSIS TYPE I
• autosomal dominant but 50% are the result of new mutations
• also known as von Recklinghausen disease
• incidence 1:3,000, mutation in NFI gene on 17q11.2 (codes for neurofibromin protein)
• learning disorders, abnormal speech development, and seizures are common
• diagnosis of NF-1 requires 2 or more of:
  - ≥6 café-au-lait spots (>5 mm if prepubertal, >1.5 cm if postpubertal)
  - ≥2 neurofibromas of any type or one plexiform neurofibroma
  - ≥2 Lisch nodules (hamartomas of the iris)
  - optic glioma
  - freckling in the axillary or inguinal region
  - a distinctive bony lesion (e.g. sphenoid dysplasia, cortical thinning of long bones)
  - a first degree relative with confirmed NF-1

NEUROFIBROMATOSIS TYPE II
• autosomal dominant
• incidence 1:33,000
• characterized by predisposition to form intracranial, spinal tumours
• diagnosed when bilateral vestibular schwannomas are found, or a first-degree relative with NF-2 and either unilateral vestibular schwannoma, or any two of the following: meningioma, glioma, schwannoma, neurofibroma, posterior subcapsular lenticular opacities.
• treatment consists of monitoring for tumour development and surgery
**Respirology**

**Approach to Dyspnea**

- determine if patient is sick or not sick; ABCs
- history: onset, previous episodes, precipitating events, associated symptoms, past medical/family history of respiratory disease
- physical exam: vitals, SpO2, evidence of cyanosis, respiratory, cardiovascular
- investigations: CBC and differential, electrolytes, BUN, Cr, NP swab, ABG, CXR, ECG (based on clinical findings)

![Figure 16. Approach to dyspnea in childhood](image)

**Upper Respiratory Tract Diseases**

- see Otolaryngology, OT44
- diseases above the thoracic inlet characterized by inspiratory stridor, hoarseness, and suprasternal retractions
- differential diagnosis of stridor: croup, bacterial tracheitis, epiglottitis, foreign body aspiration, subglottic stenosis (congenital or iatrogenic), laryngomalacia/tracheomalacia (collapse of airway cartilage on inspiration)

Lower Respiratory Tract Diseases

- obstruction of airways below thoracic inlet, produces more expiratory sounds
- classic symptom: wheezing

Differential Diagnosis of Wheezing

- common: asthma (recurrent wheezing episodes, identifiable triggers, typically over 6 yr), bronchiolitis (first episode of wheezing, usually under 1 yr), recurrent aspiration (often neurological impairment), pneumonia (fever, cough, malaise)
- uncommon: foreign body (acute unilateral wheezing and coughing), CF (prolonged wheezing, unresponsive to therapy), bronchopulmonary dysplasia (often develops after prolonged ventilation in the newborn)
- rare: CHF, mediastinal mass, bronchiolitis obliterans, tracheobronchial anomalies

Pneumonia

Etiology
- inflammation of pulmonary tissue, associated with consolidation of alveolar spaces

Clinical Presentation
- incidence is greatest in first year of life with viral causes being most common in children <5 yr
- fever, cough, tachypnea
- CXR: diffuse, streaky infiltrates bilaterally
- bacterial causes may present with cough, fever, chills, dyspnea, more dramatic CXR changes (e.g. lobar consolidation, pleural effusion)

Management
- supportive therapy: hydration, antipyretics, humidified O₂

Bronchiolitis

Definition
- LRTI, usually in children <2 yr, that has wheezing and signs of respiratory distress

Epidemiology
- the most common LRTI in infants, affects 50% of children in first 2 yr of life; peak incidence at 6 mo, winter or early spring
- increased incidence of asthma in later life

Etiology
- RSV (>50%), parainfluenza, influenza, rhinovirus, adenovirus, M. pneumoniae (rare)

Clinical Presentation
- prodrome of URTI with cough and/or rhinorrhea, possible fever
- feeding difficulties, irritability
- wheezing, crackles, respiratory distress, tachypnea, tachycardia, retractions, poor air entry; symptoms often peak at 3-4 d

Bronchodilators for Bronchiolitis
Cochrane DB Syst Rev 2010;12:CD001266
Study: Meta-analysis of prospective, randomized, double-blinded, placebo-controlled trials.
Patients: 1,912 infants (28 trials) up to 24 mo old with bronchiolitis.
Intervention: Bronchodilators (including albuterol, salbutamol, terbutaline, ipratropium bromide, and adrenergic agonists given oral, subcutaneous, or nebulized vs. placebo.
Main Outcome: Oxygen saturation.
Results: No clinically significant difference for infants treated with bronchodilators vs. placebo for bronchiolitis. Given the costs and side effects, it is not recommended to use bronchodilators as management for bronchiolitis in infants.
Investigations

- CXR (only in severe disease, poor response to therapy, chronic episode): air trapping, peribronchial thickening, atelectasis, increased linear markings
- NP swab: direct detection of viral antigen (immuno fluorescence)
- WBC can be normal

Treatment

- self-limiting disease with peak symptoms usually lasting 2-3 wk
- mild to moderate distress
  - supportive: PO or IV hydration, antipyretics for fever, regular or humidified high flow O₂
  - severe distress
    - as above ± intubation and ventilation as needed
    - consider rebetol (Ribavirin®) in high risk groups: bronchopulmonary dysplasia, CHD, congenital lung disease, immunodeficient
- monthly RSV-Ig or palivizumab (monoclonal antibody against the F-glycoprotein of RSV) is protective against severe disease in high risk groups; case fatality rate <1%
- antibiotics have no therapeutic value unless there is secondary bacterial pneumonia
  - indications for hospitalization
    - hypoxia: O₂ saturation <92% on initial presentation
    - persistent resting tachypnea >60/min and retractions after several salbutamol masks
    - past history of chronic lung disease, hemodynamically significant cardiac disease, neuromuscular problem, immunocompromised
    - young infants <6 mo old (unless extremely mild)
    - significant feeding problems
    - social problem (e.g. inadequate care at home)

Asthma

Definition

- see Respirology, R7
- characterized by recurrent episodes of airway hyperreactivity, bronchospasm, and inflammation; reversible small airway obstruction
- very common, presents most often in early childhood
- associated with other atopic diseases such as allergic rhinitis or atopid dermatitis

Clinical Presentation

- episodic bouts of wheezing, dyspnea, tachypnea, cough (usually at night/early morning, with activity, or cold exposure)
- physical exam may reveal hyper-resonant chest, prolonged expiration, wheeze

Triggers

- URTI (viral or Mycoplasma), weather (cold exposure, humidity changes), allergens (pets), irritants (cigarette smoke), exercise, emotional stress, drugs (ASA, β-blockers)

Classification

- mild: occasional attacks of wheezing or coughing (<2/wk); symptoms respond quickly to inhaled bronchodilator; never needs systemic corticosteroids
- moderate: more frequent episodes with symptoms persisting and chronic cough; decreased exercise tolerance; sometimes needs systemic corticosteroids
- severe: daily and nocturnal symptoms; frequent ED visits and hospitalizations; usually needs systemic corticosteroids

Management

- acute
  - O₂ (keep O₂ saturation >94%) and fluids if dehydrated
  - β₂-agonists: salbutamol (Ventolin®) MDI + spacer (nebulized or IV in very severe episodes with impending respiratory failure), 5 puffs (<20 kg) or 10 puffs q20min for first hour (>20 kg)
  - ipratropium bromide (Atrovent®) if severe: MDI + spacer, 3 puffs (<20 kg) or 6 puffs (>20 kg) q20min with salbutamol, or add to first 3 salbutamol masks (0.25 mg if <20 kg, 0.5mg if >20 kg)
  - steroids: prednisone (1-2 mg/kg x 5 d) or dexamethasone (0.3 mg/kg/d x 5 d or 0.6 mg/kg/d x 2 d); in severe disease, use IV steroids
  - continue to observe; can discharge patient if asymptomatic for 2-4 h after last dose
- chronic
  - education, emotional support, avoid allergens or irritants, develop an “action plan”
  - exercise program (e.g. swimming)
  - monitor respiratory function with peak flow meter (improves self-awareness of status)

Canadian Pediatric Asthma Consensus Guidelines for Assessing Adequate Control of Asthma

- Daytime symptoms <4 d/wk
- Night time symptoms <1 night/wk
- Normal physical activity
- Mild and infrequent exacerbations
- No work/school absenteeism
- Need for β-agonist <4 doses/wk
- FEV₁ or peak expiratory flow ≥90% of personal best
- Peak expiratory flow diurnal variation ≤10-15%
PFTs for children >6 yr
- reliever therapy: short acting β₂-agonists (e.g. salbutamol)
- controller therapy (first line therapy for all children): low dose daily inhaled corticosteroids
- second line therapy for children <12 yr: moderate dose of daily inhaled corticosteroids
- second line therapy for children >12 yr: leukotriene receptor antagonist OR long acting β₂-agonist in conjunction with low dose inhaled corticosteroids; leukotriene receptor antagonist monotherapy may be considered an alternative second line therapy
- severe asthma unresponsive to first and second line treatments: injection immunotherapy
- aerochamber for children using daily inhaled corticosteroids

indications for hospitalization
- ongoing need for supplemental O₂
- persistently increased work of breathing
- β₂-agonists are needed more often than q4h after 4-8 h of conventional treatment
- patient deteriorates while on systemic steroids

Cystic Fibrosis

see Respirology, R12

Etiology
- 1 per 3,000 live births, mostly Caucasians
- autosomal recessive, CFTR gene found on chromosome 7 (ΔF508 mutation in 70%, but >1,600 different mutations identified) resulting in a dysfunctional chloride channel on the apical membrane of cells
- leads to relative dehydration of airway secretions, resulting in impaired mucociliary transport and airway obstruction

Clinical Presentation
- neonatal: meconium ileus, prolonged jaundice, antenatal bowel perforation
- infancy: pancreatic insufficiency with steatorrhea and FTT (despite voracious appetite), anemia, hypoproteinemia, hypotension, hypochloremic metabolic alkalosis and hypotonic dehydration
- childhood: heat intolerance, wheezing or chronic cough, recurrent chest infections (S. aureus, P. aeruginosa, H. influenzae), hemoptysis, nasal polyps, distal intestinal obstruction syndrome, rectal prolapse, clubbing of fingers
- older patients: COPD, infertility (males), decreased fertility (female)

Investigations
- sweat chloride test x 2 (>60 mEq/L)
  - false positive tests: malnutrition, atopic dermatitis, hypothyroidism, hypoparathyroidism, GSD, adrenal insufficiency, G6PD, Klinefelter syndrome, technical issues, autonomic dysfunction, familial cholestasis syndrome
  - false negative tests: technical problem with test, malnutrition, skin edema, mineralocorticoids

Management
- nutritional counselling: high calorie diet, pancreatic enzyme replacements, fat soluble vitamin supplements
- management of chest disease: physiotherapy, postural drainage, exercise, bronchodilators, aerosolized DNase and inhaled hypertonic saline, antibiotics (e.g. cephalosporin, clavulanic acid, ciprofloxacin, inhaled tobramycin depending on sputum C&S), lung transplantation
- genetic counselling

Complications
- respiratory failure, pneumothorax (poor prognostic sign), cor pulmonale (late), pancreatic fibrosis with DM, gallstones, cirrhosis with portal HTN, infertility (male)
- early death (current median survival in Canada is 46.6 yr)

</table>

- must rule out infection, malignancy, and acute orthopedic conditions

## History
- demographics (age, gender)
- pattern of onset and progression of symptoms (including acuity and chronicity)
- morning stiffness, limp/weight-bearing status, night pain
- joint involvement (type, distribution) + spine (axial) involvement
- extra-articular manifestations and systemic symptoms
- functional status – activities of daily living
- family history (arthritis, IBD, psoriasis, spondyloarthopathies, uveitis, bleeding disorders, sickle cell anemia)
- past medical illness, intercurrent infection, travel, sick contact history, joint injury

## Physical Exam
- growth parameters
- screening examination (pediatric gait, arms, legs, spine exam)
- joint exam: inspection/palpation (swelling, erythema, warmth, tenderness, deformity), ROM
- adjacent structures (bone, tendon, muscle, skin)
- leg length
- neurologic exam

## Investigations
- basic: CBC and differential, blood smear, ESR, CRP, x-ray
- as indicated: blood (ANA, RF, culture, viral/bacterial serology, CK, PTT, sickle cell screen, immunoglobulins, complement), urinalysis, synovial fluid (cell count, Gram stain, culture), TB skin test, imaging, bone marrow aspiration, slit lamp exam

**Red Flags for Limb Pain**
- Fever, pinpoint pain/tenderness, pain out of proportion to degree of inflammation, night pain, weight loss, erythema
Growing Pains

**Epidemiology**
- age 2-12 yr, M=F

**Clinical Presentation**
- diagnosis of exclusion
- intermittent, non-articular pain in childhood with normal physical exam findings
- pain at night, often bilateral and limited to the calf, shin, or thigh; typically short-lived
- relieved by heat, massage, mild analgesics
- child is well, asymptomatic during the day, no functional limitation
- possible family history of growing pains

**Management**
- lab investigations not necessary if typical presentation; reassurance and supportive management

Transient Synovitis of the Hip

- benign, self-limited disorder, usually occurs after URTI, pharyngitis, AOM

**Epidemiology**
- age 3-10 yr, M>F

**Clinical Presentation**
- afebrile or low-grade fever, pain typically occurs in hips, knees (referred from hip); painful limp but full ROM (pain not as pronounced as in joint or bone infections)
- symptoms resolve over 7-10 d

**Investigations**
- WBC within normal limits; ESR and CRP may be mildly elevated
- joint effusions may be seen on imaging
- diagnosis of exclusion (rule out septic arthritis and osteomyelitis)

**Treatment**
- symptomatic and anti-inflammatory medications

Septic Arthritis and Osteomyelitis

- MEDICAL EMERGENCY
- see Orthopedics, OR10

Juvenile Idiopathic Arthritis

- a heterogenous group of conditions characterized by persistent arthritis in children <16 yr
- diagnosis: arthritis in ≥1 joint(s); duration ≥6 wk; onset age <16 yr old; exclusion of other causes of arthritis; classification defined by features/number of joints affected in the first 6 mo of onset

Systemic Arthritis (Still’s Disease)
- onset at any age, M=F
- once or twice daily fever spikes (≥38.5°C) ≥2 d/wk; children usually acutely unwell during fever episodes
- extra-articular features: erythematous “salmon-coloured” maculopapular rash, lymphadenopathy, hepatosplenomegaly, leukocytosis, thrombocytosis, anemia, serositis
• arthritis may occur weeks to months later
• high ESR, CRP, WBC, platelet count

Oligoarticular Arthritis (1-4 joints)
• onset early childhood, F>M
• persistent: affects no more than 4 joints during the disease course
• extended: affects more than 4 joints after the first 6 mo
• typically affects large joints: knees > ankles, elbows, wrists; hip involvement unusual
• ANA positive ~60-80%, RF negative
• screening eye exams for asymptomatic anterior uveitis (occurs in ~30%)
• complications: knee flexion contracture, quadriceps atrophy, leg-length discrepancy, growth disturbances

Polyarticular Arthritis (5 or more joints)
• RF negative
  ▪ onset: 2-4 yr and 6-12 yr, F>M
  ▪ symmetrical involvement of large and small joints of hands and feet, TMJ, cervical spine
• RF positive
  ▪ onset: late childhood/early adolescence, F>M
  ▪ similar to the aggressive form of adult rheumatoid arthritis
  ▪ severe, rapidly destructive, symmetrical arthritis of large and small joints
  ▪ may have rheumatoid nodules at pressure points (elbows, knees)
  ▪ unremitting disease, persists into adulthood

Enthesitis-Related Arthritis
• onset: late childhood/adolescence, M>F
• arthritis and/or enthesitis (inflammation at the site where tendons or ligaments attach to the bone)
• weight bearing joints, especially hip and intertarsal joints
• risk of developing ankylosing spondylitis in adulthood

Psoriatic Arthritis
• onset: 2-4 yr and 9-11 yr, F>M
• arthritis and psoriasis OR arthritis and at least two of:
  ▪ dactylitis, nail pitting or other abnormalities, or family history of psoriasis in a 1st degree relative
  ▪ asymmetric or symmetric small or large joint involvement

Management
• goals of therapy: eliminate inflammation, prevent joint damage, promote normal growth and development as well as normal function, minimize medication toxicity
• exercise to maintain ROM and muscle strength
• multidisciplinary approach: OT/PT, social work, orthopedics, ophthalmology, rheumatology
• 1st line drug therapy: NSAIDs, intra-articular corticosteroids
• 2nd line drug therapy: DMARDs (methotrexate, sulfasalazine, leflunamide), corticosteroids (acute management of severe arthritis, systemic symptoms of JIA, topical eye drops for uveitis), biologic agents

Reactive Arthritis
• see Rheumatology, RH24
• arthritis (typically the knee) follows bacterial infection, especially with Salmonella, Shigella, Yersinia, Campylobacter, Chlamydia, and most commonly Streptococcus (post-streptococcal reactive arthritis)
• typically resolves spontaneously
• may progress to chronic illness or Reiter’s syndrome (urethritis, conjunctivitis)

Lyme Arthritis
• see Infectious Diseases, ID23
• caused by spirochete Borrelia burgdorferi
• incidence highest among 5-10 yr olds
• do not treat children <8 yr old with doxycycline (may cause permanent tooth discoloration)
Systemic Lupus Erythematosus

- see Rheumatology, RH11
- autoimmune illness affecting multiple organ systems
- incidence 1/1,000, more commonly age >10, F:M = 10:1
- childhood-onset SLE vs. adult-onset SLE: children have more active disease, are more likely to have renal disease, and children receive more intensive drug therapy and have a poorer prognosis

Vasculitides

HENOPH-SCHÖNLEIN PURPURA
- most common vasculitis of childhood, peak incidence 4-10 yr, M:F = 2:1
- vasculitis of small vessels
- often have history of URTI 1-3 wk before onset of symptoms

Clinical Presentation
- clinical tetrad: 1) palpatble purpura, 2) abdominal pain, 3) arthritis
- skin: palpatble, non-thrombocytopenic purpura in lower extremities and buttocks, edema, scrotal swelling
- joints: arthritis/arthralgia involving large joints associated with painful edema
- GI: abdominal pain, GI bleeding, intussusception
- renal: microscopic hematuria, IgA nephropathy, proteinuria, HTN, renal failure in <5%

Management
- mainly supportive
- anti-inflammatory medications for joint pain, corticosteroids for select patients
- monitor for protein on urinalysis every month for 6 mo, checking for renal disease, which may develop late (immunosuppressive therapy if severe)

Prognosis
- self-limited, resolves within 4 wk
- recurrence in about one-third of patients
- long-term prognosis dependent on severity of nephritis

KAWASAKI DISEASE
- acute vasculitis of unknown etiology (likely triggered by infection)
- medium-sized vasculitis with predilection for coronary arteries
- most common cause of acquired heart disease in children in developed countries
- peak age: 3 mo-5 yr; Asians > Blacks > Caucasians

Diagnostic Criteria
- fever persisting ≥5 d AND ≥4 of the following features
  1. bilateral, non-exudative conjunctival injection
  2. oral mucous membrane changes (fissured lips, strawberry tongue, injected pharynx)
  3. changes of the peripheral extremities
     - acute phase: extremity changes including edema of hands and feet or erythema of palms or soles
     - subacute phase: periungual desquamation
  4. polymorphous rash
  5. cervical lymphadenopathy >1.5 cm in diameter (usually unilateral)
- exclusion of other diseases (e.g. scarlet fever, measles)
- atypical Kawasaki disease: fever persisting ≥5 d and 2-3 of the above criteria
- further evaluation dictated by CRP, ESR, and supplemental laboratory criteria

Management
- initial therapy: IVIG (2g/kg) and high (anti-inflammatory) dose of ASA
- once afibrile >48 hours: low (anti-platelet) dose of ASA until platelets normalize, or longer if coronary artery involvement
- IVIg within 10 d of onset reduces risk of coronary aneurysm formation
- baseline 2D-Echo and follow up periodic 2D-Echo (usually at 2, 6 wk)

Complications
- coronary artery vasculitis with aneurysm formation occurs in 20-25% of untreated children,
  <5% if receive IVIg within 10 d of fever
- 50% of aneurysms regress within 2 yr
- anticoagulation for multiple or large coronary aneurysms
- risk factors for coronary disease: male, age <1 or >9 yr, fever >10 d, Asian or Hispanic ethnicity, thrombocytopenia, hyponatremia

Diagnostic Criteria for Kawasaki Disease

| Warm CREAM | Fever ≥5 d with ≥4 of:

Skin Lesions and Masses

Differential Diagnosis of Skin Lesions/Masses

- for background information and medical management (see Dermatology, D5)
- for biopsy techniques, see Skin Biopsy Types and Techniques, PL7

Surgical Management of Malignant Skin Lesions

- surgical treatment for all malignant skin lesions involve total excision of the primary lesion
- excision margin of lesion depends on the type of lesion, the lesion diameter and (for melanoma) the lesion depth
- for decisions regarding reconstruction using flaps or skin grafts, see Reconstruction, PL11

Precursors of Malignant Lesions

**Surgical Techniques**

**Sutures and Suturing**

**ANESTHESIA**
- irrigate before injecting anesthetic, followed by debridement

**Table 5. Toxic Limit and Duration of Action (1 cc of 1% solution contains 10 mg lidocaine)**

<table>
<thead>
<tr>
<th>Without Epinephrine</th>
<th>With Epinephrine (vasoconstrictor, limits bleeding)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lidocaine (Xylocaine[^a])</td>
<td>5 mg/kg, lasts 45-60 min</td>
</tr>
<tr>
<td>Bupivicaine (Marcaine[^c]) for longer analgesic effect</td>
<td>2 mg/kg, lasts 2-4 h</td>
</tr>
</tbody>
</table>

- example: if you have a 70 kg patient, the toxic limit for 1% lidocaine without epinephrine is
  - 5 mg x 70 kg = 350 mg TOXIC LIMIT
  - 350 mg ÷ 10 mg/cc = 35 cc MAX BOLUS INJECTION of 1% lidocaine without epinephrine (may add more after 30 min)

**IRRIGATION AND DEBRIDEMENT**
- irrigate copiously with a physiologic solution such as Ringer’s lactate or normal saline to remove surface clots, foreign material, and bacteria
- use a 19 gauge needle and 35 cc syringe to generate ~18 psi when irrigating (~8 psi will reach the wound)
- debride all obviously devitalized tissue, irregular or ragged wounds must be excised to produce sharp wound edges that will assist healing when approximated
- wounds left unapproximated ≥8 h should be debrided to ensure wound edges are optimized for healing

**SUTURES**
- use of a particular suture material is highly dependent on surgeon preference; however, skin should be closed with a non absorbable material when traumatic mechanisms are involved
- suture materials are divided into absorbable vs. non-absorbable and monofilament vs. braided

**Table 6. Suture Materials: Absorbable vs. Non-absorbable and Monofilament vs. Multifilament**

<table>
<thead>
<tr>
<th>Suture Materials</th>
<th>Uses</th>
<th>Examples</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absorbable</td>
<td>Deep sutures under short-term tension</td>
<td>Plain gut[^a], Vicryl[^a], Polysorb[^a]</td>
<td>loses at least 50% of their strength in 4 wk; eventually absorbed</td>
</tr>
<tr>
<td></td>
<td>Skin closure in children</td>
<td>Nylon, polypropylene (Prolene), stainless steel</td>
<td>Lower likelihood of wound dehiscence, more difficult to tie</td>
</tr>
<tr>
<td>Non-absorbable</td>
<td>Sites of long-term tension</td>
<td>Monosof[^a], Monocryl[^a], Biosyn[^a]</td>
<td>Slides through tissue with less friction; more memory/stiffness</td>
</tr>
<tr>
<td>Monofilament</td>
<td>Everyday use and optimal for contaminated and infected wounds (lower likelihood of bacterial trapping in suture material)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Multifilament</td>
<td>AVOID in contaminated wounds (increased likelihood of bacterial trapping)</td>
<td>Vicryl[^a] and Silk</td>
<td>Less memory/stiffness thus easier to work with</td>
</tr>
</tbody>
</table>

**Basic Suturing Techniques**

**Basic Suture Methods**
- simple interrupted: can be used in almost all situations
- sub-cuticular: good cosmetic result but weak, used in combination with deep sutures; not used in trauma
- vertical mattress: for areas difficult to evert (e.g. dorsum of the hand)
- horizontal mattress: evertng, time saving
- continuous over and over (i.e. “running”, “baseball stitch”): time saving, good for hemostasis

**Basic Principles**
- minimize tissue trauma: follow curve of needle, insert and exit at 90 degrees to the wound edge, handle wound edges gently (use toothed forceps), use just enough tension to approximate edges (do not strangulate)
- use appropriate needles and sutures
- ensure good cosmesis

---

[^a]: Baseer Khan, Tabby Lulham 2010

---

© Baseer Khan, Tabby Lulham 2010
Other Skin Closure Materials
- tapes: may be indicated for superficial wounds and those with opposable edges. Tape cannot be used on actively bleeding wounds. When placed across the incision, will prevent surface marks and can be used primarily or after surface sutures have been removed. Tape burns may occur if there is excessive tension or swelling around the incision
- skin adhesives: e.g. 2-octylcyanoacrylate (e.g. Dermabond®) works well on small areas without much tension or shearing; may cause irreversible tattooing
- staples: steel-titanium alloys that incite minimal tissue reaction (healing is comparable to wounds closed by suture)

Excision
- plan your incision along relaxed skin tension lines to minimize appearance of scar
- use elliptical incision to prevent "dog ears" (heaped up skin at end of incision) so the length of the ellipse should be approximately 3x the width
- if needed, undermine skin edges to decrease wound tension
- use layered closure including dermal sutures when wound is deeper than superficial (decreases tension)

Skin Biopsy Types and Techniques
SHAVE BIOPSY
- used for superficial lesions where sampling of the full thickness of the dermis is not necessary or practical
- most suitable lesions for shave biopsies are either elevated above the skin or have pathology confined to the epidermis (e.g. seborrheic or actinic keratoses, skin tags, warts, and superficial basal cell or squamous cell carcinomas)
- rapid, requires little training, and does not require sutures for closure
- will leave a circular scar
- can leave an indented scar
- heals by secondary intent (moist dressings should be used)
- should not be used for pigmented lesions – an unsuspected melanoma cannot be properly staged if partially removed

INCISIONAL BIOPSY
- can either be a punch biopsy or can be an ellipse including the lesion
- gives pathologists a portion of the lesion and the border with normal skin too

PUNCH BIOPSY
- involves the removal of a core-shaped piece of tissue, performed with round, disposable knives ranging in diameter from 2-10 mm
- allows sampling of the deep dermis
- can be used for the diagnosis and treatment of small pigmented lesions and atypical moles
- punch biopsy wounds can be closed with suture or left to heal by secondary intention. Punches greater than 3 mm may produce scarring and are best closed with one or two sutures
- has low incidence of infection, bleeding, nonhealing, significant scarring

EXCISIONAL BIOPSY
- performed for lesions that require complete removal for diagnostic or therapeutic purposes
- performed for lesions that cannot be adequately punch biopsied due to size, depth, or location
- requires the greatest amount of expertise and time
- always requires sutures for closure

TECHNIQUE
General
- all biopsies performed in clinic are done using aseptic technique, but are not sterile
- sterile gloves are indicated for biopsies and excisions in all patients

Preparing the Site
- common skin antisepsics (betadine, chlorhexidine) can be used to prepare the biopsy site
- chlorhexidine is used in concentrations ranging from 0.5-4%. This higher concentration cannot be used on the face as it could get into the eyes or ears and may burn or cause damage. Most chlorhexidine preps also contain alcohol which can be flammable, so allow to dry before the biopsy and certainly before using any cautery
- mark the intended lesion and surgical margins with a surgical marker since they may be temporarily obliterated following injection of the anesthetic
- for all biopsies, a sterile drape technique is indicated. A fenestrated surgical drape is placed around the biopsy site after the area is cleansed and anesthetized

Anesthesia
- most commonly used local anesthetic is 1% or 2% lidocaine (with epinephrine)
- small amounts of epinephrine are added to constrict blood vessels, decrease bleeding, prolong anesthesia, and limit lidocaine toxicity. The local with epinephrine can be injected directly into the lesion
• local anesthetics with epinephrine may be used anywhere in the body (including the digits – except if the digits have been significantly injured and could have vascular compromise – e.g. saw injury)
• epinephrine should be avoided in patients with history of vascular compromise
• a field block should be performed for larger lesions by placing a ring of anesthetic around the surgical site, advancing and injecting through a site that has been previously anesthetized

## Wounds

### Causal Conditions

- laceration: cut or torn tissue
- abrasion: superficial skin layer is removed, variable depth
- contusion: injury caused by forceful blow to the skin and soft tissue; entire outer layer of skin intact yet injured
- avulsion: tissue/limb forcefully separated from surrounding tissue, either partially or fully; “de-gloving”
- puncture wounds: cutaneous opening relatively small as compared with depth (e.g. needle)
  - includes bite wounds
- crush injuries: caused by compression
- thermal and chemical wounds

### Principles of Wound Healing

• wound: disruption of the normal anatomical relationships of tissue as a result of injury

#### FACTORS INFLUENCING WOUND HEALING

</tbody>
</table>
ABNORMAL HEALING

Hypertrophic Scar
- scar remains roughly within boundaries of original scar
- red, raised, widened, frequently pruritic
- common sites: back, shoulder, sternum
- treatment: scar massage, pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision if other options fail (however, may still recur)

Keloid Scar
- scar grows outside boundaries of original scar
- red, raised, widened, frequently pruritic
- caused by 1. genetic factors, 2. endocrine factors and/or 3. excess tension on wound or delayed closure (as in burn wounds)
- common sites: back, shoulder, sternum, angle of mandible
- treatment: multimodal therapy, including pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision with post-surgical management if other options fail (however, may still recur), fractional carbon dioxide ablative laser, radiation

Chronic Wound
- fails to achieve primary wound healing within 4-6 wk
- common chronic wounds include diabetic, pressure and venous stasis ulcers
- treatment: may heal with meticulous wound care; may also require surgical intervention
- Marjolin’s ulcer: squamous cell carcinoma arising in a chronic wound secondary to genetic changes caused by chronic inflammation → consider biopsy of chronic wound

WOUND HEALING

Primary (1st) Healing (First Intention)
- definition: wound closure by direct approximation of edges within hours of wound creation (i.e. with sutures, staples, skin graft, etc.)
- indication: recent (<6 h, longer with facial wounds), clean wounds
- contraindications: animal/human bites (except on face), crush injuries, infection, long time lapse since injury (>6-8 h), retained foreign body

Secondary (2nd) Healing/Spontaneous Healing (Second Intention)
- definition: wound left open to heal spontaneously (epithelialization 1 mm/d from wound margins in concentric pattern), contraction (myofibroblasts) and granulation – maintained in inflammatory phase until wound closed; requires dressing changes; inferior cosmetic result
- indication: when 1st closure not possible or indicated (see Primary Healing)

Tertiary (3rd) Healing/Delayed Primary Healing (Third Intention)
- definition: intentionally interrupt healing process (e.g. with packing), then wound can be closed at 4-10 d post-injury after granulation tissue has formed and there is <10^5 bacteria/gram of tissue
- indication: contaminated (high bacterial count), long time lapse since initial injury, severe crush component with significant tissue devitalization, closure of fasciotomy wounds
- prolongation of inflammatory phase decreases bacterial count and lessens chance of infection after closure

Contaminated and Infected Wounds

Definitions
- contamination: the presence of non-replicating microorganisms within a wound
- colonization: the presence of replicating microorganisms within a wound
- infection: greater than 10^6 microorganisms in a wound without intact epithelium, a wound may also be infected with small amounts of a very virulent organism (e.g. GBS)

Management of Acute Contaminated Wound (<24 h)
- cleanse and irrigate open wound with physiologic solution (NS or RL) using sufficient pressure
- evaluate for injury to underlying structures (vessels, nerve, tendon and bone)
- control active bleeding
- debridement: removal of foreign material, devitalized tissue, old blood
  - surgical debridement: blade and irrigation if indicated
- systemic antibiotics are commonly indicated for obvious infection. Risk factors include wound older than 8 h, severely contaminated, human/animal bites, immunocompromised, involvement of deeper structures (e.g. joints, fractures)
- ± tetanus toxoid 0.5 mL IM ± tetanus immunoglobulin 250 U deep IM (see Table 7 and Table 8)
• ± post-exposure treatment of
  • hepatitis B, HIV, hepatitis C (if titres confirmed at 6 mo)
• re-evaluate in 24-48 h for signs of superficial or deep infection
  • if evidence of infection, open infected portion of wound by removing sutures (i.e. erythema, warmth, pain, discharge), swab sample for culture and sensitivity, irrigate wound and allow healing secondary intention

<td>No</td>
</tr>
</tbody>
</table>

  * 0.5 mL of combined tetanus and diptheria toxoids + acellular pertussis
  ** Tetanus immune globulin, 250 U given at a separate site from Td/Tdap

Management of Contaminated Wounds (>24 h, including ulcers)

• irrigation and debridement
• traumatic tattooing can occur if foreign materials left in wound
• systemic antibiotics indicated if there is concern of infection (e.g. redness, swelling, pain, clinically unwell)
• topical antimicrobials: beneficial for minor wounds, but no additional benefit for wounds requiring systemic antibiotics. May aid in healing of chronic wounds
• closure: final closure via secondary intention (most common), delayed wound closure (3º closure), skin graft or flap; successful closure depends on bacterial count of ≤10⁵/cm³ prior to closure and frequent dressing changes

BITES

• see Emergency Medicine, ER47

Dog and Cat Bites

• pathogens: Pasteurella multocida, S. aureus, S. viridans
• investigations: same as for human bites
• treatment: Clavulin® (500 mg PO q8h started immediately – amoxicillin + clavulanic acid)
  • ± rabies prophylaxis if animal has symptoms of rabies or unknown animal
  • ± rabies Ig (20 IU/kg around wound, or IM) and 1 of the 3 types of rabies vaccines (1.0 mL IM in deltoid, repeat on days 3, 7, 14, 28)
  • aggressive irrigation with debridement
  • healing by secondary intention is mainstay of treatment
  • only consider primary closure for bite wounds on the face; otherwise primary closure is contraindicated
  • contact Public Health if animal status unknown

Human Bites

• pathogens: Staphylococcus > α-hemolytic Streptococcus > Eikenella corrodens > Bacteroides
• mechanism: most commonly over dorsum of MCP from a punch in mouth; “fight-bite”
• serious, as mouth has 10⁹ microorganisms/mL, which get trapped in joint space when fist unclenches and overlying skin forms an air-tight covering ideal for anaerobic growth – can lead to septic arthritis
• investigations
  • radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  • culture for aerobic and anaerobic organisms, Gram stain
• treatment
  • urgent surgical exploration of joint, drainage and debridement of infected tissue
  • wound must be copiously irrigated
  • Clavulin® 500 mg PO q8h or (if penicillin allergy) clindamycin 300 mg PO q6h + ciprofloxacin 500 mg PO q12h + secondary closure
  • splint
**Dressings**

- there is no one dressing for any given type of wound. Dressing selection depends on the wound characteristics and surgeon preference
  - as the wound progresses through healing it will require different types of dressings, therefore, routine inspection is recommended
  - principles of dressings
    - moist vs. dry wounds
      - purpose of dressings should be to promote moist wound healing (i.e. moistening dry wounds or removing excess exudate/blood from wet wounds)
    - clean vs. infected wounds
      - clean wounds can be dressed with non-adherent dressing (which is non-adhering to epithelializing tissue); requires secondary dressing
      - infected wounds can be dressed with iodine gauze, silver-containing, or antimicrobial dressings
    - wide-based vs. cavitary/tunneling wounds
      - cavitary or tunnelling wounds (i.e. through a fascial layer) can be packed with saline-soaked (non-infected), betadine-soaked (infected) ribbon gauze, or other easily retrievable one-piece moisture providing dressing

**Table 9. Recommended Dressings for Wound Type**

</table>

Table adapted from Grabb & Smith’s Plastic Surgery, 6th ed. Chapter 3, Table 3.3

**Reconstruction**

**RECONSTRUCTION LADDER**

**Definition**
- an approach to wound management with successively more complex methods of treatment
- surgeons should start with the least complex method and progressively increase in complexity as appropriate

**SKIN GRAFTS**

**Definition**
- skin that is harvested from a donor site and transferred to the recipient site and that does not carry its own blood supply. Survival requires the generation of new blood vessels from the recipient site bed. They are classified according to the depth of dermis they contain: full thickness (entire epidermis + dermis) vs. split-thickness (epidermis + partial dermis)

**Donor Site Selection**
- must consider size, hair pattern, texture, thickness of skin, and colour (facial grafts best if taken from “blush zones” above clavicle e.g. pre/post auricular or neck)
- partial thickness grafts usually taken from inconspicuous areas (e.g. buttocks, lateral thighs, etc.)

**Partial Thickness Skin Graft Survival**
- 3 phases of skin graft “take”
  1. plasmatic imbibition: diffusion of nutrition from recipient site (first 48 h)
  2. inosculation: vessels in graft connect with those in recipient bed (day 2-3)
  3. neovascular ingrowth: graft revascularized (day 3-5)
- requirements for survival
  - bed: well-vascularized (unsuitable: bone, tendon, heavily irradiated, infected wounds, etc.)
  - contact between graft and recipient bed: fully immobile (decreased shearing and hematoma formation)
  - staples, sutures, splinting, and appropriate dressings (pressure) are used to prevent movement of graft and hematoma or seroma formation
  - site: low bacterial count (<10⁵/cm³, to prevent infection)
Classification of Skin Grafts

1. by species
   - autograft: from same individual
   - allograft (homograft): from same species, different individual
   - xenograft (heterograft): from different species (e.g. porcine)

2. by thickness: see Table 10

Table 10. Skin Grafts

<table>
<thead>
<tr>
<th></th>
<th>Split Thickness Skin Graft</th>
<th>Full Thickness Skin Graft</th>

<tr>
<td>Healing of Donor Site</td>
<td>Re-epithelialization via dermal appendages in graft and wound edges</td>
<td>Primary closure</td>
</tr>
<tr>
<td>Re-Harvesting</td>
<td>~10 d (faster on scalp)</td>
<td>N/A</td>
</tr>
<tr>
<td>Graft Take</td>
<td>More reliable and better survival; shorter nutrient diffusion distance</td>
<td>Lower rate of survival (thicker, slower vascularization)</td>
</tr>
<tr>
<td>Contraction*</td>
<td>Less 1st contraction, greater 2nd contraction (less with thicker graft)</td>
<td>Greater 1st contraction, less 2nd contraction</td>
</tr>
<tr>
<td>Aesthetic</td>
<td>Poor</td>
<td>Good</td>
</tr>
<tr>
<td>Comments</td>
<td>Can be meshed for greater area; Allows for extravasation of blood/serum</td>
<td>May use on face and fingers</td>
</tr>
<tr>
<td>Advantages</td>
<td>Takes well in less favourable conditions; Can cover a larger area</td>
<td>Resists contraction, better colour match; May use on face and fingers</td>
</tr>
<tr>
<td>Disadvantages</td>
<td>Contracts significantly, abnormal pigmentation, high susceptibility to trauma</td>
<td>Requires well vascularized bed; Must remove fat from graft before application</td>
</tr>
<tr>
<td>Uses</td>
<td>Large areas of skin, granulating tissue beds</td>
<td>Face (colour match), site where thick skin or decreased contraction is desired (e.g. finger)</td>
</tr>
</tbody>
</table>

*Primary: immediate reduction in size upon harvesting; Secondary: reduction in size once graft placed on wound bed

- mesh graft (split of full thickness skin graft)
  - advantages
    - prevents accumulation of fluids (e.g. hematoma, seroma)
    - covers a larger area
    - best for contaminated recipient site
  - disadvantages
    - poor cosmesis ("alligator hide" appearance)
    - has significant contraction

OTHER GRAFTS

FLAPS

- definition: tissue transferred from one site to another with a known blood supply (random, pedicled or named); not dependent on neovascularization, unlike a graft
- may consist of: skin, subcutaneous tissue, fascia, muscle, bone, other tissue (e.g. omentum)
- classification: based on blood supply to skin (random, axial) and anatomic location (local, regional, distant)
- indications for flaps
  - replaces tissue loss due to trauma or surgery (reconstruction)
  - provides skin and temporary soft tissue coverage through which surgery can be carried out later
  - to aid healing or treatment of infection by providing vascularized tissue to a poorly vascularized bed
• **complications**: flap loss due to hematoma, seroma, infection, poor flap design, extrinsic compression (dressing too tight) or vascular failure/thrombosis, fat necrosis (in free and pedicled flaps)

**Random Pattern Flaps**
- blood supply by dermal and subdermal plexus to skin and subdermal tissue with random vascular supply
- limited length:width ratio to ensure adequate blood supply (typically 3:1)
- flap choice is often a combination of available tissue, type of tissue needed, location of reconstruction site with respect to donor site, and surgeon preference
- types
  - **rotation**: semicircular tissue rotated around a pivot point for defect closure; commonly used on sacral pressure sores
  - **transposition**: tissue is transposed around a pivot point from one location to another; commonly used on certain areas of the face using adjacent areas of excess skin laxity
  - **Z-plasty**: two triangular flaps are repositioned; used to reorient a scar, lengthen the line of a scar or to break up a scar
  - **advancement flaps** (V-Y, Y-V): defect is closed with unidirectional tissue advancement
    - single/bipedicle V-Y flaps: wounds with lax surrounding tissue; the pedicle is the deep tissue underlying the flap

**Axial Pattern Flaps (Arterialized)**
- flap contains a well-defined artery and vein
- allows greater length:width ratio (3-6:1)
- types
  - **peninsular flap**: skin and vessel intact in pedicle
  - **island flap**: vessel intact, pedicle is better defined
  - **free flap**: vascular supply anastomosed at recipient site by microsurgical techniques
- can be sub-classified according to tissue content of flap
  - e.g. musculocutaneous/myocutaneous (e.g. transverse rectus abdominal myocutaneous) vs. fasciocutaneous

**Free Flaps**
- transplanting expendable donor tissue from one part of the body to another by isolating and dividing a dominant artery and veins to a flap and performing a microsurgical anastomosis between these and the vessels in the recipient wound
- survival rates >95%
- types: muscle and skin (common), bone, jejunum, omentum, fascia
  - e.g. radial forearm, scapular, latissimus dorsi

---

</tr>
<tr>
<td>Cellulitis</td>
<td>Full thickness with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Fasciitis</td>
<td>Fascia</td>
</tr>
<tr>
<td>Myositis</td>
<td>Muscle</td>
</tr>
</tbody>
</table>

#### Erysipelas

**Definition**
- acute skin infection that is more superficial than cellulitis

**Etiology**
- typically caused by Group A β-hemolytic *Streptococcus*

**Clinical Features**
- intense erythema, induration, and **sharply demarcated borders** (differentiates it from other skin infections)

**Treatment**
- penicillin or first generation cephalosporin (e.g. cefazolin or cephalaxin)

#### Cellulitis

**Definition**
- non-suppurative infection of skin and subcutaneous tissues

**Etiology**
- skin flora most common organisms: *S. aureus*, β-hemolytic *Streptococcus*
- immunocompromised: Gram-negative rods and fungi

**Clinical Features**
- source of infection
  - trauma, recent surgery
  - PVD, DM – cracked skin in feet/toes
  - foreign bodies (IV, orthopedic pins)
  - systemic symptoms (fever, chills, malaise)
  - pain, tenderness, edema, erythema with poorly defined margins, regional lymphadenopathy
- can lead to ascending lymphangitis (visible red streaking in skin proximal to area of cellulitis)

**Investigations**
- CBC, blood cultures
- culture and Gram stain a collection/aspirate from wound if open wound
- plain radiographs cannot distinguish cellulitis from necrotizing fasciitis or gas gangrene but may help distinguish osteomyelitis

**Treatment**
- antibiotics: first line – cephalaxin 500 mg PO q6h or cloxacillin 500 mg PO q6h x 7 d; if complicated (e.g. lymphangitis, DM, severe infection, oral antibiotic therapy failure) consider IV cefazolin 1-2 g q8h or V cloxacillin, IV penicillin
- outline area of erythema to monitor success of treatment
- immobilize and splint (hands)
Necrotizing Fasciitis

Definition
- rapidly spreading, very painful infection of the fascia with necrosis of surrounding tissues
- some bacteria create gas that can be felt as crepitus and be seen on x-rays
- infection spreads rapidly along deep fascial plane and is limb and life threatening

Etiology
- Type I: polymicrobial (less aggressive)
- Type II: monomicrobial, usually β-hemolytic Streptococcus

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
  - edema, tenderness, ± crepitus (subcutaneous gas from anaerobes)
  - overlying skin changes including blistering and ecchymoses
  - hyponatremia and hyperglycemia are common findings
  - patients may look deceptively well at first, but may rapidly become very sick/toxic
  - late findings
    - skin turns dusky blue and black (secondary to thrombosis and necrosis)
    - induration, formation of bullae
    - cutaneous gangrene, subcutaneous emphysema

Investigations
- a clinical diagnosis
- CT scan only if suspect it is not necrotizing fasciitis (looking for abscess, gas collection, myonecrosis and possible source of infection)
- severely elevated CK: usually means myonecrosis (late sign)
- bedside incision and exploration when ruling out conditions, clinical presentation is not supportive or difficult exam
- during incisional biopsy, often see "dish water pus" (Group A infection) and a hemostat easily passed along fascial plane (fascial biopsy to rule out in equivocal situations)

Treatment
- vigorous resuscitation (ABCs)
- urgent surgical debridement: remove all necrotic tissue, copious irrigation
- IV antibiotics: as appropriate for clinical scenario; consider penicillin 4 million IU IV q4h and/or clindamycin 900 mg IV q6h until final cultures available (the combination can be synergistic if Group A strep)
- possible role for IVIg (especially in Group A strep, adjuvant treatment on a case by case basis)
- urgent consultation with infectious disease specialist is recommended

Ulcers

Lower Limb Ulcers

Traumatic Ulcers (Acute)
- failure of wound to heal, usually due to compromised blood supply and unstable scar, secondary to pressure or bacterial colonization/infection
- usually over bony prominence ± edema ± pigmentation changes ± pain
- treatment: debridement of ulcer and compromised tissue, left to heal via secondary intention with dressings, may need reconstruction with local or distant flap in select cases, vascular status of limb must be assessed clinically and via vascular studies (i.e. ABI, duplex doppler)

Non-Traumatic Ulcers (Chronic)

</tr>
</tbody>
</table>

Pressure Ulcers

Common Sites
- over bony prominences; 95% on lower body

Stages of Development
1. hyperemia: disappears 1 h after pressure removed
2. ischemia: follows 2-6 h of pressure
3. necrosis: follows >6 h of pressure
4. ulcer: necrotic area breaks down – N.B. skin is like tip of an iceberg

Classification (National Pressure Ulcer Advisory Panel 2014)
- Stage I: nonblanchable erythema present >1 h after pressure relief, skin intact
- Stage II: partial-thickness skin loss
- Stage III: full-thickness skin loss into subcutaneous tissue
- Stage IV: full-thickness skin loss into muscle, bone, tendon, or joint
  - if an eschar is present, must fully debride before staging possible

Prevention
- good nursing care (clean dry skin, frequent repositioning), special beds or pressure relief surface, proper nutrition, activity, early identification of individuals at risk (e.g. immobility, incontinence, paraplegia, immunocompromised, DM etc.)

Treatment
- depends on individual patient and condition
- treat underlying medical issues including nutrition
- continue with preventative measures (pressure relief and assess for pressure points e.g. wheelchairs)
- wound debridement, moisture retentive or antimicrobial dressing, regular reassessment
- topical antimicrobials at treating physician’s discretion, systemic antibiotics for infections
- assess for possible reconstruction

Complications
- cellulitis, osteomyelitis, sepsis, gangrene
Burns

Burn Injuries

Causal Conditions
- thermal (flame contact, scald)
- chemical
- radiation (UV, medical/therapeutic)
- electrical

Most Common Etiology
- children: scald burns
- adults: flame burns

Table 15. Skin Function and Burn Injury

</tbody>
</table>

Pathophysiology of Burn Wounds

- amount of tissue destruction is based on temperature, time of exposure, and specific heat of the causative agent
- zone of hyperemia: vasodilation from inflammation; entirely viable, cells recover within 7 d; contributes to systemic consequences seen with major burns
- zone of stasis (edema): decreased perfusion; microvascular sludging and thrombosis of vessels results in progressive tissue necrosis → cellular death in 24-48 h without proper treatment
  - factors favouring cell survival: moist, aseptic environment, rich blood supply
  - zone where appropriate early intervention has most profound effect in minimizing injury
- zone of coagulation (ischemia): no blood flow to tissue → irreversible cell damage → cellular death/necrosis

Diagnosis and Prognosis

- burn size
  - % of TBSA burned: rule of 9s for 2° and 3° burns only (children <10 yr old use Lund-Browder chart)
  - for patchy burns, surface area covered by patient's palm (fingers closed) represents approximately 1% of TBSA
- age: more complications if <3 or >60 yr old
- depth: difficult to assess initially – history of etiologic agent and time of exposure helpful (see Table 16)
- location: face and neck, hands, feet, perineum are critical areas requiring special care of a burn unit (see Indications for Transfer to Burn Centre, PL18)
- inhalation injury: can severely compromise respiratory system
- associated injuries (e.g. fractures)
- comorbid factors (e.g. concurrent disability, alcoholism, seizure disorders, chronic renal failure) can exacerbate extent of injury

Prognosis best determined by
- burn size (TBSA)
- age of patient
- presence/absence of inhalational injury
Table 16. Burn Depth (1st, 2nd, 3rd degree)

<table>

<tr>
<td>Full Thickness</td>
<td>Third degree</td>
<td>Through epidermis and dermis injury to underlying tissue structures (e.g. muscle, bone)</td>
<td>Insensate (nerve endings destroyed), hard leathery eschar that is black, grey, white, or cherry red in colour, hairs do not stay attached, may see thrombosed veins</td>
</tr>
</tbody>
</table>
Indications for Transfer to Burn Centre

American Burn Association Criteria
- patients with partial or full-thickness burns that involve the hands, feet, genitalia, face, eyes, ears, and/or major joints or perineum
- partial thickness burns ≥20% TBSA in patients aged 10-50 yr old
- partial thickness burns ≥10% TBSA in children aged ≤10 or adults aged ≥50 yr old
- full thickness burns ≥5% TBSA in patients of all ages
- electrical burns, including lightening (internal injury underestimated by TBSA)
- chemical burns
- inhalation injury (high risk of mortality and may lead to respiratory distress)
- burn injuries in patients with medical comorbidities, could complicate management and recovery
- any patient with simultaneous trauma plus burns should be stabilized for trauma first, then triaged appropriately to burn centre
- any patients with burn injury and who will require special emotional, social, and rehabilitation intervention
- children with burns in a hospital not equipped with pediatric care specialists

Acute Care of Burn Patients
- adhere to ATLS protocol
- resuscitation using Parkland formula to restore plasma volume and cardiac output, Parkland formula is a starting estimate and patients may require more volume. Other formulas exist but the Parkland formula is predominately used in North America
  - 4 cc RL/kg/% TBSA over first 24 h (1/2 within first 8 h of sustaining burn, 1/2 in next 16 h)
- extra fluid administration required if
  - burn >80% TBSA
  - 4° burns
  - associated traumatic injury
  - electrical burn
  - inhalation injury
  - delayed start of resuscitation
  - pediatric burns
- monitor resuscitation
  - urine output is best measure: maintain at >0.5 cc/kg/h (adults) and 1.0 cc/kg/h (children <12 yr)
  - maintain a clear sensorium, HR <120/min, MAP >70 mmHg
- burn specific care
  - relieve respiratory distress: intubation and/or escharotomy
  - Escharotomy in circumferential extremity burn
  - prevent and/or treat burn shock: 2 large bore IVs for fluid resuscitation
  - insert Foley cather to monitor urine output
  - identify and treat immediate life-threatening conditions (e.g. inhalation injury, CO poisoning)
  - determine TBSA affected first, since depth is difficult to determine initially (easier to determine after 24 h)
- tetanus prophylaxis if needed
  - all patients with burns >10% TBSA, or deeper than superficial partial thickness, need 0.5 cc tetanus toxoid
  - also give 250 U of tetanus Ig if prior immunization is absent/unclear, or the last booster >10 yr ago
- baseline laboratory studies (Hb, U/A, BUN, CXR, electrolytes, ECG, cross-match if traumatic injury, ABG, carboxyhemoglobin)
- cleanse, debride, and treat the burn injury (antimicrobial dressings)
- early excision and grafting important for outcome

Respiratory Problems
- 3 major causes
  - burn eschar encircling chest
    - distress may be apparent immediately
    - perform escharotomy to relieve constriction
  - CO poisoning
    - may present immediately or later
    - treat with 100% O2 by facemask (decreases half-life of carboxyhemoglobin from 210 to 59 min) until carboxyHb <10%

Inhalation Injuries 101
- Indicators of inhalation injury
  - Injury in a closed space
  - Facial burn
  - Singed nasal hair/eyebrows
  - Soot around nares/oral cavity
  - Hoarseness
  - Conjunctivitis
  - Tachypnea
  - Carbon particles in sputum
  - Elevated blood CO levels (i.e. brighter red)
- Suspected inhalation injury requires immediate intubation due to impending airway edema; failure to diagnose inhalation injury can result in airway swelling and obstruction, which, if untreated, can lead to death
- Neither CXR or ABG can be used to rule out inhalation injury
- Direct bronchoscopy now used for diagnosis
- Signs of CO poisoning (headache, confusion, coma, arrhythmias)
- smoke inhalation leading to pulmonary injury
  - chemical injury to alveolar basement membrane and pulmonary edema (insidious onset)
  - risk of pulmonary insufficiency (up to 48 h) and pulmonary edema (48-72 h)
  - watch for secondary bronchopneumonia (3-25 d) leading to progressive pulmonary insufficiency
  - intubate patient with any signs of inhalation injuries

## Burn Wound Healing

### Table 17. Burn Shock Resuscitation (Parkland Formula)

| Hour 0-24 | 4 cc RL/kg/% TBSA with 1/2 of total in first 8 h from time of injury and 1/2 of total in next 16 h from time of injury |
| Hour 24-30 | 0.35-0.5 cc plasma/kg/TBSA |
| >Hour 30 | D5W at rate to maintain normal serum sodium |

*Do not forget to add maintenance fluid to resuscitation*

### Table 18. Burn Wound Healing

<table>
<thead>
<tr>
<th>Depth</th>
<th>Healing</th>
</tr>
</thead>
<tbody>
<tr>
<td>First degree (No scarring; complete healing)</td>
<td></td>
</tr>
<tr>
<td>Second degree (Superficial partial)</td>
<td>Spontaneously re-epithelialize in 7 to 14 d from retained epidermal structures ± residual skin discoloration</td>
</tr>
<tr>
<td>Deep second degree (Deep partial)</td>
<td>Re-epithelialize in 14-35 d from retained epidermal structures Hypertrophic scarring frequent</td>
</tr>
<tr>
<td>Third degree (Full thickness)</td>
<td>Re-epithelialize from the wound edge</td>
</tr>
<tr>
<td>Fourth degree</td>
<td>Often results in amputations If not requiring amputation, needs flap for coverage after debridement (do not re-epithelialize – cannot graft)</td>
</tr>
</tbody>
</table>

## Treatment

- 3 stages
  1. assessment: depth determined
  2. management: specific to depth of burn and associated injuries
  3. rehabilitation

- first degree
  - treatment aimed at comfort
    - topical creams (pain control, keep skin moist) ± aloe
    - oral NSAIDs (pain control)

- superficial second degree
  - daily dressing changes with topical antimicrobials (such as polysporin); leave blisters intact unless circulation impaired or unless over joint inhibiting motion

- deep second degree and third degree
  - prevent infection and sepsis (significant cause of death in burn patients)
    - most common organisms: *S. aureus, P. aeruginosa* and *C. albicans*
      - day 1-3 (rare): Gram-positive
      - day 3-5: Gram-negative (*Proteus, Klebsiella*)
    - topical antimicrobials: treat colonized wounds (from skin flora, gut flora or caregiver)
  - remove dead tissue
    - surgically debride necrotic tissue, excise to viable (bleeding) tissue

### Table 19. Antimicrobial Dressings for Burns

<table>
<thead>
<tr>
<th>Antibiotic</th>
<th>Pain with Application</th>
<th>Penetration</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Silver nitrate (0.5% solution)</td>
<td>None</td>
<td>Minimal</td>
<td>May cause methemoglobinemia, stains (black), leaches sodium from wounds</td>
</tr>
<tr>
<td>Nanocrystalline silver-coated dressing (Acticoat®)</td>
<td>None or transient</td>
<td>Medium, does not penetrate eschar</td>
<td>May stain, producing a pseudoeschar or facial discoloration (argyria-like symptoms); raised liver enzymes</td>
</tr>
<tr>
<td>Silver sulfadiazine (cream) (Silvadene®)</td>
<td>Minimal</td>
<td>Medium, penetrates eschar poorly</td>
<td>Slowed healing, leukopenia, mild inhibition of epithelialization</td>
</tr>
<tr>
<td>Mafenide acetate (solution/cream) (Sulfamylon®)</td>
<td>Moderate</td>
<td>Well, penetrates eschar</td>
<td>Mild inhibition of epithelialization, may cause metabolic acidosis with wide application</td>
</tr>
</tbody>
</table>

## Risk Factors for Infection of Burn Wounds

### Patient Related
- Extent >30% TBSA
- Depth: full-thickness and deep partial-thickness
- Patient age (higher risk with very young and very old)
- Comorbidities
- Wound dryness
- Wound temperature
- Secondary impairment of blood flow to wound
- Acidosis

### Microbial Factors
- Density >10⁵ organisms per gram tissue
- Motility
- Virulence and metabolic products (endotoxin, exotoxin, permeability factors, other factors)
- Antimicrobial resistance
• early excision and grafting is the mainstay of treatment for deep/full thickness burns
• initial dressing should decrease bacterial proliferation
• prevention of wound contractures: pressure dressings, joint splints, early physiotherapy

Other Considerations in Burn Management

Vascular Permeability and Edema
Immunosuppression
Renal Failure (2^nd to ↓ Renal Blood Flow)
SEVERE BURN

Altered Hemodynamics (↓ CO, ↑ SVR)
Hypermetabolism
Progressive Pulmonary Insufficiency
Increased Gut Mucosal Permeability
(GI Bleed Risk)

Figure 21. Systemic effects of severe burns

• nutrition
  - hypermetabolism: TBSA >40% have BMR 2-2.5x predicted
  - consider nutritional supplementation e.g. calories, vitamin C, vitamin A, Ca^{2+}, Zn^{2+}, Fe^{2+}
• immunosuppression and sepsis
  - must keep bacterial count <10^5 bacteria/g of tissue (blood culture may not be positive)
  - signs of sepsis: sudden onset of hyper/hypothermia, unexpected CHF or pulmonary edema, development of ARDS, ileus >48 h post-burn, mental status changes, azotemia, thrombocytopenia, hypofibrinogenemia, hyper/hypoglycemia (especially if burn >40% TBSA)
• GI bleed may occur with burns >40% TBSA (usually subclinical)
  - treatment: tube feeding or NPO, antacids, H2 blockers (preventative)
  - renal failure secondary to under resuscitation, drugs, myoglobin, etc.
  - progressive pulmonary insufficiency
    - can occur after: smoke inhalation, pneumonia, cardiac decompensation, sepsis
• wound contracture and hypertrophic scarring (outcomes optimized with timely wound closure, splinting, pressure garments) and physiotherapy

Special Considerations

CHEMICAL BURNS
• major categories: acid burns, alkaline burns, phosphorous burns, chemical injection injuries
• common agents: cement, hydrofluoric acid, phenol, tar
• mechanism of injury: chemical solutions coagulate tissue protein leading to necrosis
  - acids → coagulation necrosis
  - alkalines → saponification followed by liquefactive necrosis
• severity related to: type of chemical (alkali worse than acid), temperature, volume, concentration, contact time, site affected, mechanism of chemical action, degree of tissue penetration
• burns are deeper than they initially appear and may progress with time

Treatment (General)
• ABCs, monitoring
• remove contaminated clothing and brush off any dry powders before irrigation
• irrigation with water for 1-2 h under low pressure (contraindicated in heavy metal burns, such as sodium, potassium, magnesium, and lithium; in these cases soak in mineral oil instead)
• inspect eyes, if affected: wash with saline and refer to ophthalmology
• inspect nails, hair and webspaces
• correct metabolic abnormalities and tetanus prophylaxis if necessary
• local wound care 12 h after initial dilution (debridement)
• wound closure same as for thermal burn
• beware of underestimated fluid resuscitation, renal, liver, and pulmonary damage

Special Burns and Treatments

<table>
<thead>
<tr>
<th>Burn Type</th>
<th>Treatment Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acid Burn</td>
<td>Water irrigation, followed by dilute solution of sodium bicarbonate</td>
</tr>
<tr>
<td>Hydrofluoric Acid</td>
<td>Water irrigation; clip fingernails to avoid acid trapping; topical calcium gel ± subcutaneous injection of calcium gluconate ± 10% calcium gluconate IV depending on amount of exposure and pain</td>
</tr>
<tr>
<td>Sulfuric Acid</td>
<td>Treat with soap/lime prior to irrigation, as direct water exposure produces extreme heat</td>
</tr>
<tr>
<td>Tar</td>
<td>Remove with repeated application of petroleum-based antibiotic ointments (e.g. Polysporin®)</td>
</tr>
</tbody>
</table>
ELECTRICAL BURNS
- depth of burn depends on voltage and resistance of the tissue (injury more severe in tissues with high resistance)
- often presents as small punctate burns on skin with extensive deep tissue damage which requires debridement
- electrical burns require ongoing monitoring as latent injuries can occur
- watch for system specific damages and abnormalities
  - abdominal: intraperitoneal damage
  - bone: fractures and dislocations especially of the spine and shoulder
  - cardiopulmonary: anoxia, ventricular fibrillation, arrhythmias
  - muscle: myoglobinuria indicates significant muscle damage → compartment syndrome
  - neurological: seizures and spinal cord damage
  - ophthalmology: cataract formation (late complication)
  - renal: ATN resulting from toxic levels of myoglobin and hemoglobin
  - vascular: vessel thrombosis → tissue necrosis (increased Cr, K+ and acidity), decrease in RBC (beware of hemorrhages/delayed vessel rupture)
- Treatment
  - ABCs, primary and secondary survey, treat associated injuries
  - beware of cardiac arrhythmias (continue cardiac monitoring)
  - monitor: hemochromogenuria, compartment syndrome, urine output
  - wound management: topical agent with good penetrating ability (silver sulfadiazine or mafenide acetate)
  - debride non-viable tissue early and repeat prn (every 48 h) to prevent sepsis
  - amputations frequently required

</tbody>
</table>

Compartment Syndrome
Watch out for these signs with a closed or open injury: tense, painful extremity (worse on passive stretch), paresthesia/paralysis, pallor, distal pulselessness (often late in process), and contracture (irreversible ischemia)
Intracompartmental pressures can be measured (normal pressure = up to 12 mmHg), but a clinical diagnosis is an indication for an emergent fasciotomy; if untreated, end result is ischemic contracture of the extremity (Volkmann’s contracture)

Figure 22. Testing profundus (FDP) – inserts at distal phalanx
Figure 23. Testing superficialis (FDS) – inserts at middle phalanx
Table 20. Key Features of the History and Physical Exam of the Injured Hand in the Emergency Department (continued)

<table>
<thead>
<tr>
<th>Structure</th>
<th>Examination</th>
</tr>
</thead>
</table>
| **Motor Function** | Flex DIP of index finger to test the anterior interosseous (AIN) branch of the median nerve  
Touch the tip of the index finger to the thumb trying to break through (“OK sign”)  
Thumb to ceiling with palm up |
| Median nerve | Ulnar nerve  
Extrinsic muscles: flex DIP of little finger  
Intrinsic muscles: abduct index finger ("Peace sign") or patient able to hold piece of paper between adducted fingers and resist pulling |
| Radial nerve | Extrinsic muscles: extend thumb ("thumb’s up") and wrist |
| **Range of Motion** | Assess active and passive range of motion of wrist  
extension/extension/ulnar/radial deviation, finger abduction/adduction/flexion/extension, thumb flexion/extension/adduction/adduction/circumflexion |
| Tendons, bones, joints, nerves | FDP  
Stabilize PIP in extension, ask patient to flex fingers (at DIP) |
| FDS | Stabilize non-exam fingers in extension (neutralizes FDP) and ask patient to flex examination finger |
| **Palpation** | Bones  
Focal tenderness or abnormal alignment |
| Joints | Instability may indicate ligamentous injury or dislocation |

**General Management**

**Nerves**
- test the nerve function BEFORE putting in local anesthesia
- direct repair for a clean injury within 14 d and without concurrent major injuries → otherwise secondary repair
- epineural repair of all digital nerves with minimal tension
- post-operative: dress wound, elevate hand and immobilize
- Tinel’s sign (cutaneous percussion over the repaired nerve) produces paresthesias and defines level of nerve regeneration
  - Wallerian degeneration occurs in the first 2 wk, which is why there is no Tinel’s sign till after this time period
  - a peripheral nerve regenerates at 1 mm/d
  - paresthesias felt at a area of percussion because re-growth of myelin (Schwann cells) is slower than axonal re-growth → percussion on exposed free-end of axon generates paresthesia

**Vessels**
- often associated with nerve injury (anatomical proximity)
- control bleeding with direct pressure and hand elevation
- if digit devascularized, optimal repair within 6 h
- close skin then dress, immobilize, and splint hand with fingertips visible
- monitor colour, capillary refill, skin turgor, fingertip temperature post-revascularization

**Tendons**
- most tendon lacerations require primary repair
- many extensors are repaired in the emergency room, flexors are repaired in the operating room within 2 wk
- avoid excessive immobilization after repair (specific protocols for flexors, 2-3 wk for extensors) to minimize stiffness and facilitate rehabilitation

**Bones**
- see Fractures and Dislocations, PL25

**Nailbed**
- remove nail to examine underlying nailbed under digital block anesthesia
- irrigate wound and nail thoroughly
- suture repair of nailbed with chromic suture
- replace cleaned nail, which acts as splint for any underlying distal phalangeal fracture and prevents adhesion formation between nail fold and nailbed

---

**Approach to Hand Lacerations**
- **TIN AX**
  - Tetanus prophylaxis
  - Irrigate with NS (copious irrigation and debridement in a timely manner)
  - NPO (NPO only if you are considering replanting, otherwise most operations are done as elective procedures)
  - Antibiotic prophylaxis (controversial – most require no ABx, mainly needed for animal bites)
  - X-rays

**Allen’s Test**: You need to exsanguinate the hand by having the patient open and close the hand. Then, while patient’s hand is firmly closed, occlude both radial and ulnar arteries. Once fist is open, release either artery and assess collateral flow

**Hand Exam**
- Never blindly clamp a bleeding vessel as nerves are often found in close association with vessels
- Never explore any volar hand wound in the ER
- Arterial bleeding from a volar digital laceration may indicate nerve laceration (nerves in digits are superficial to arteries)

**High pressure injection injury** is deceptively benign-looking (small pinpoint hole on finger pad) often with few clinical signs. Intense pain and tenderness, along the course the foreign material travelled, is present a few hours after the injury. Definitive treatment is exposure and removal of foreign material.
Hand Infections

Principles
- trauma is most common cause
- 5 cardinal signs: rubor (red), calor (hot), tumour (swollen), dolor (painful) and functio laesa (loss of function)
- 90% caused by Gram-positive organisms
- most common organisms (in order) – S. aureus, S. viridans, Group A Streptococcus, S. epidermidis, and Bacteroides melaninogenicus (MRSA is becoming more common)

TYPES OF INFECTIONS

Deep Palmar Space Infections
- uncommon, there are 9 spaces in the hand, the most commonly involved are thenar or mid-palm space (treated in the OR)

Felon
- definition: subcutaneous abscess in the fingertip that commonly occurs following a puncture wound into the pad of digit; may be associated with osteomyelitis (skin to compartment syndrome and can lead to skin necrosis)
- treatment: elevation, warm soaks, cloxacillin 500 mg PO q6h (if in early stage); if obvious abscess or pressure on the overlying skin or failure to resolve with conservative measures, then needs I&D; take cultures/gram stain and PO cloxacillin

Flexor Tendon Sheath Infection
- Staphylococcus > Streptococcus > Gram-negative rods
- definition: acute tenosynovitis commonly caused by a penetrating injury and can lead to tendon necrosis and rupture if not treated; it is often suppurative; however, early on there can be very little pus
- clinical features: Kanavel’s 4 cardinal signs
  1. point tenderness along flexor tendon sheath (earliest and the most sensitive and specific)
  2. severe pain on passive extension of DIP (second most important)
  3. fusiform swelling of entire digit
  4. flexed posture (increased comfort)
- treatment
  - OR incision and drainage, irrigation, IV antibiotics, and resting hand splint until infection resolves

Herpetic Whitlow
- HSV-1, HSV-2
- definition: painful vesicle(s) around fingertip
  - often found in medical/dental personnel and children
- clinical features: can be associated with fever, malaise and lymphadenopathy
- patient is infectious until lesion has completely healed
- treatment: routine culture and viral prep protection (cover), consider oral acyclovir; do not break blisters, as this can spread infection

Paronychia
- acute = Staphylococcus; chronic = Candida
- definition: infection (granulation tissue) of soft tissue around fingernail (beneath eponychial fold)
- etiology
  - acute paronychia: a “hangnail”, artificial nails, and nail biting
  - chronic paronychia: prolonged exposure to moisture
- treatment
  - acute paronychia: warm compresses and cephalaxin 500 mg PO q6h if caught early and drainage if abscess present – can usually drain with a #11 blade directed into the abscess from underneath the paronychial fold
  - chronic paronychia: anti-fungals with possible debridement and marsupialization, removal of nail plate

Amputations

Hand or Finger
- emergency management: injured patient and amputated part require attention
  - patient: x-rays (stump and amputated part), NPO, clean wound and irrigate with NS, dress stump with nonadherent, cover with dry sterile dressing, tetanus and antibiotic prophylaxis (cephalosporin/erythromycin)
  - amputated part: x-rays, gently irrigate with RL, wrap amputated part in a NS/RL soaked sterile gauze and place inside waterproof plastic bag, place in a container, then place container on ice
• indications for replantation
  - age: children often better results than adults
  - level of injury: proximal, thumb and multiple digit amputations are higher priority
  - nature of injury: clean cut injuries have higher successful replantation rate; avulsion and crush injuries are relative contraindications to replant
  - if replant contraindicated manage stump with revision amputation
    - would only allow a fingertip injury to heal by secondary intention

## Tendons

### Common Extensor Tendon Deformities

<table>
<thead>
<tr>
<th>Injury</th>
<th>Definition</th>
<th>Zone</th>
<th>Etiology/Clinical Features</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mallet Finger</td>
<td>DIP flexed with loss of active extension</td>
<td>1</td>
<td>There are bony and non-bony mallets. Bony: Fracture of distal phalanx distal to tendon insertion. Non-bony: Forced flexion of the extended DIP leading to extensor tendon rupture at DIP (e.g. sudden blow to tip of the finger).</td>
<td>Splint DIP in extension for 6 wk followed by 2 wk of night splinting; if inadequate improvement after 6 wk, check splinting routine and recommend 4 more wk of continuous splinting. If there is a bony component that is displaced the patient may require ORIF.</td>
</tr>
<tr>
<td>Boutonniere Deformity</td>
<td>PIP flexed, DIP hyperextended</td>
<td>3</td>
<td>Injury or disease affecting the extensor tendon insertion into the dorsal base of the middle phalanx. Associated with RA or trauma (laceration, volar dislocation, acute forceful flexion of PIP)</td>
<td>Splint PIP in extension and allow active DIP motion.</td>
</tr>
<tr>
<td>Swan Neck Deformity</td>
<td>PIP hyperextended, DIP flexed</td>
<td>3</td>
<td>Trauma (PIP volar plate injury). Associated with RA and old, untreated mallet deformity.</td>
<td>Splint to prevent PIP hyperextension or DIP flexion. Consider arthrodesis/arthroplasty.</td>
</tr>
</tbody>
</table>

De Quervain’s Tenosynovitis (zone 7; most common cause of radial wrist pain)
- definition: inflammation in 1st extensor compartment (APL and EPB)
- clinical features
  - +ve Finkelstein’s test (pain over the radial styloid induced by making fist, with thumb in palm, and ulnar deviation of wrist)
  - pain localized to the 1st extensor compartment
  - tenderness and crepitation over radial styloid may be present
  - differentiate from CMC joint arthritis (CMC joint arthritis will have a positive grind test, whereby crepitus and pain are elicited by axial pressure to the thumb)
- treatment
  - mild: NSAIDs, splinting and steroid injection into the tendon sheath (successful in over 60% of cases)
  - severe: surgical release of stenotic tendon sheaths (APL and EPB); remember there may be 2 or more sheaths

Ganglion Cyst
- definition
  - fluid-filled synovial lining that protrudes between carpal bones or from a tendon sheath; most commonly carpal in origin
  - most common soft tissue tumour of hand and wrist (60% of masses)
- clinical features
  - most common around scapholunate ligament junction
  - 3 times more common in women than in men
  - more common in younger individuals
  - can be large or small – may drain internally so size may wax and wane
  - often non-tender although tenderness increased when cyst smaller (from increased pressure within smaller cyst sac)
• treatment
  ▪ conservative treatment: do nothing
  ▪ aspiration (recurrence rate 65%)
  ▪ consider operative excision of cyst and stalk (recurrence is possible)
  ▪ steroids if painful (done in combination with aspiration)

Common Flexor Tendon Deformities
• flexor tendon zones (important for prognosis of tendon lacerations)
  ▪ “no-man’s land”
    ▪ between distal palmar crease and mid-middle phalanx
    ▪ zone where superficialis and profundus lie ensheathed together
  ▪ recovery of glide very difficult after injury

Stenosing Tenosynovitis (trigger finger/thumb)
• definition: inflammation of synovium causes size discrepancy between tendon and sheath/pulley (most commonly at A-1 pulley) = locking of thumb or finger in flexion/extension
• etiology: idiopathic or associated with RA, DM, hypothyroidism and gout
• clinical features
  ▪ thumb, ring and long fingers most commonly affected
  ▪ patient complains of catching, snapping or locking of affected finger
  ▪ tenderness to palpation/nodule at palmar aspect of MCP over A-1 pulley
  ▪ women are 4 times more likely than men to be affected
• conservative treatment
  ▪ NSAIDs
  ▪ steroid injection
  ▪ injections less likely to be successful in patients with DM or symptoms greater than 6 mo
  ▪ splint
• surgical treatment
  ▪ indicated if no relief of symptoms or minimal relief with steroids
  ▪ incise A-1 flexor tendon pulley to permit unrestricted, full active finger motion

Fractures and Dislocations

• for fracture principles, see Orthopedics, OR4

FRACTURES
• about 90% of hand fractures are stable in flexion (splint to prevent extension)
• position of function (like a hand holding a pop can)
  ▪ wrist extension 15°
  ▪ MCP flexion 45°
  ▪ IP flexion (slight)
  ▪ thumb abduction/rotation
  ▪ done if you wanted to immobilize a fracture but are were unsure if there were other injuries
  ▪ contraindications: post repair of flexor tendons, median/ulnar nerve injury
  ▪ stiffness secondary to immobilization is the most important complication; T x = early motion

Distal Phalanx Fractures
• most commonly fractured bone in the hand
• usual mechanism is crush injury and thus accompanied by soft tissue injury
• subungual hematoma is common and must be decompressed if painful by removing the nail
• treatment consists of 3 wk of digital splinting (with IP joint movement preserved)

Proximal and Middle Phalanx Fractures
• check for: rotation, scissoring (overlap of fingers on making a fist), shortening of digit
  ▪ undisplaced or minimally displaced: closed reduction (if extra-articular) buddy tape to neighbouring stable digit, elevate hand, motion in guarded fashion early, splinted for 2-3 wk
  ▪ displaced, non-reducible, not stable with closed reduction, or rotational or scissoring deformity: percutaneous pins (K-wires) or ORIF, and splint

Metacarpal Fractures
• generally accept varying degrees of deviation before reduction required: up to 10° (D2), 20° (D3), 30° (D4), or 40° (D5)
• Boxer’s fracture (extra-articular): acute angulation of neck of metacarpal of little finger into palm
  ▪ mechanism: blow on the distal-dorsal aspect of closed fist
  ▪ loss of prominence of metacarpal head, volar displacement of head
  ▪ check for scissoring of fingers on making a fist
  ▪ up to 30-40° angulation may be acceptable
  ▪ closed reduction should be considered to decrease the angle
  ▪ if stable ulnar gutter splint for 2-3 wk

Grading classification for Stenosing Tenosynovitis
• Grade I (Pre-triggering)- Pain/ tenderness over the A1 pulley with a hx of catching although not catching on exam
• Grade II (Active)- Demonstrable catching, but the patient can extend the finger
• Grade III (Passive)- Grade IIIa: catching requiring passive extension. Grade IIIb is the inability to actively flex
• Grade IV (Contracture)- Catching with a fixed flexion contracture of the proximal interphalangeal joint
• **Bennett's fracture (intra-articular):** fracture/dislocation of the base of the thumb metacarpal
  - unstable fracture
  - abductor pollicis longus pulls MC shaft proximally and radially causing adduction of thumb
  - treat with percutaneous pinning, thumb spica x 6 wk
• **Rolando's fracture (intra-articular):** T- or Y-shaped fracture of the base of the thumb metacarpal
  - treated like a Bennett's fracture

### DISLOCATIONS
- must be reduced as soon as possible
- dislocation vs. subluxation
  - dislocation: severe injury where articular surfaces of a joint are no longer in contact with one another
  - subluxation: articular surfaces of a joint are partially out of place, but then go back into place (partial dislocation, often unstable)

### PIP and DIP Dislocations (PIP more common than DIP)
- usually dorsal dislocation (commonly from hyperextension)
- if closed dislocation: closed reduction and splinting (30° flexion for PIP and full extension for DIP) or buddy taping and early mobilization (prolonged immobilization causes stiffness)
- open injuries are treated with wound care, closed or open reduction, irrigation and debridement, and antibiotics

### MCP Dislocations (relatively rare)
- dorsal dislocations much more common than volar dislocations
- dorsal dislocation of proximal phalanx on metacarpal head; most commonly index finger (hyperextension)
- two types of dorsal dislocation
  - simple (reducible with manipulation): treat with 2-4 wk of splinting at 30° MCP flexion
  - complex (volar plate blocks reduction): treat with open reduction and A1 pulley release + extension-blocking splint at 30° flexion (2 wk) then 10° flexion (2 wk)

### Ulnar Collateral Ligament (UCL) Injury
- forced abduction of thumb (e.g. ski pole injury)
- **skier's thumb:** acute UCL injury
- **gamekeeper's thumb:** chronic UCL injury
- **evaluation:** radially deviate thumb MCP joint in full extension and at 30° flexion and compare with non-injured hand. UCL rupture is presumed if injured side deviates more than 30° in full extension or more than 15° in flexion
- **Stener's lesion:** the UCL has bony attachments to the adductor aponeurosis and the proximal ligament can displace while the distal attachment remains deep to the aponeurosis, forming a barrier that blocks healing and leads to chronic instability; requires surgery

### Dupuytren's Disease

#### Definition
- contraction of longitudinal palmar fascia, forming nodules (usually painless), fibrous cords and eventually flexion contractures at the MCP and interphalangeal joints
- flexor tendons not involved
- Dupuytren's diathesis: early age of onset, strong family history, and involvement of sites other than palmar aspect of hand

#### Epidemiology
- genetic disorder, unusual in patients from African and Asian countries, high incidence in northern Europeans, men > women, often presents in 5th-7th decade of life, associated with but not caused by alcohol use and DM

#### Clinical Features
- order of digit involvement (most common to least common): ring > little > long > thumb > index
- may also involve feet (Ledderhose's) and penis (Peyronie's – see Urology, U30)

#### Treatment
- stages
  1. palmar pit or nodule: no surgery
  2. palpable band/cord with no limitation of extension of either MCP or PIP: no surgery
  3. lack of extension at MCP or PIP: surgical fasciectomy indicated
  4. irreversible periarticular joint changes/scarring: surgical treatment possible but poorer prognosis compared to stage 3
Carpal Tunnel Syndrome

**Definition**
- median nerve compression at the level of the flexor retinaculum as opposed to pronator teres syndrome (compressive neuropathy at the level of the elbow)

**Etiology**
- median nerve entrapment at wrist
- primary cause is idiopathic
- secondary causes: space occupying lesions (tumours, hypertrophic synovial tissue, fracture callus, and osteophytes), metabolic and physiological (pregnancy, hypothyroidism, acromegaly, and RA), infections, neuropathies (associated with DM or alcoholism), and familial disorders
- job/hobby related repetitive trauma, especially forced wrist flexion

**Epidemiology**
- female:male = 4:1, most common entrapment neuropathy

**Clinical Features**
- sensory loss in median nerve distribution (see Figure 4)
- discriminative touch often lost first
- classically, patient awakened at night with numb/painful hand, relieved by shaking/dangling/ rubbing
- decreased light touch and 2-point discrimination, especially fingertips
- advanced cases: thenar wasting/weakness due to involvement of the motor branch of the nerve
- ± Tinel's sign (tingling sensation on percussion of nerve)
- ± Phalen's sign (wrist flexion induces symptoms)

**Investigations**
- clinical diagnosis
- NCV and EMG may confirm, but do not exclude, the diagnosis

**Treatment**
- avoid repetitive wrist and hand motion, wrist splints at night and when repetitive wrist motion required
- conservative: night time splinting to keep wrist in neutral position
- medical: NSAIDs, local corticosteroids injection, oral corticosteroids
- surgical decompression: transverse carpal ligament incision to decompress median nerve
- indications for surgery: numbness and tingling ± sensory loss, weakness ± muscle atrophy, unresponsive to conservative measures
- complications of surgery: injury to median motor branch, palmar cutaneous branch or superficial transverse vascular arch, local pain (pain at wrist flexion)

Rheumatoid Hand

- see Rheumatology: RH8

Brachial Plexus

**Etiology**
- common causes of brachial plexus injury: complication of childbirth and trauma
- other causes of injury: compression from tumours, ectopic ribs

**Common Palsies**

Development and Validation of Diagnostic Criteria for Carpal Tunnel Syndrome

**J Hand Surg 2006;31:919-924**

**Purpose:** To develop a clinical diagnostic criteria for carpal tunnel syndrome that modeled the clinical diagnostic practices of experts.

**Methods:** Out of 57 clinical findings associated with CTS, eight were ranked highly by a panel of expert clinicians. Using 256 case histories, a panel of experts decided whether a case did or did not have a diagnosis of CTS. This diagnosis represented the dependent variable for a logistic regression model, to which the eight clinical findings were applied. The regression model was then validated against the consensus of a second panel on the diagnosis of CTS for the case histories.

**Results/Conclusions:** The correlation between the probability of CTS predicted by the regression model and the panel of clinicians was 0.71. Clinical diagnostic criteria that contributed significantly to the model were:

1. Numbness and tingling in median nerve distribution
2. Nocturnal numbness
3. Weakness and/or atrophy of the thenar musculature
4. Tinel’s sign
5. Phalen’s test
6. Loss of 2-point discrimination

A Cochrane Review looked at non-surgical management of carpal tunnel and found that there is significant short-term benefit from oral steroids, splinting, ultrasound, yoga, and carpal bone mobilization.

Cochrane Database Systematic Review 2003: CD001279

Radiographic Evolution of the Rheumatoid Hand

**Earliest Sign:** erosion of the ulnar styloid

**Progression:** characterized by symmetrical joint space narrowing and erosions of the carpal bones, MCP and PIP (with DIP relatively spared)

**Late Stage:** Swan neck and Boutonniere deformities
Differential Diagnosis of Adult Acquired Brachial Plexus Palsies

- trauma (blunt, penetrating)
- thoracic outlet syndrome
  - neurogenic: associated with cervical rib; compression of C8/T1
  - vascular: pain or sensory symptoms without cervical rib; cessation of radial pulse with provocative maneuvers
- tumour
  - schwannoma: well-defined margins makes it easier for total resection
  - neurofibromas: associated with neurofibromatosis type I
  - other: e.g. Pancoast syndrome (apical lung tumour)
- neuropathy (compressive, post-irradiation, viral, diabetic, idiopathic)

Investigations

- EMG
- CT myelogram: controversial, although some people think that it is better than MRI for identification of nerve root avulsion and identification of pseudomeningocele. Important for pre-operative identification of patients likely to require neurotisation procedures (especially for patients with blunt trauma)
- timing for investigations and surgery is important. First studies are likely not done until 6 wk after a closed injury; however, any open injury will go to the OR for immediate exploration

Management

<table>

<tr>
<td>Sharp or vascular injury</td>
<td>Explore immediately in OR</td>
</tr>
</tbody>
</table>

Craniofacial Injuries

- low velocity vs. high velocity injuries determine degree of damage
- fractures cause bruising, swelling and tenderness → loss of function
- frequency: nasal > zygomatic > mandibular > maxillary
- management: can wait 5-10 d for swelling to decrease before ORIF required

Approach to Facial Injuries

- ATLS protocol
- inspect, palpate, clinical assessment for injury to underlying structures (e.g. facial nerve)
- tetanus prophylaxis
- radiological evaluation
- wound irrigation with NS/RL and remove foreign materials
- conservative debridement of detached or nonviable tissue
- repair when patient’s general condition allows (soft tissue injury: <8 h preferable)
- suspect C-spine injury with any facial trauma. C-spine evaluation should be done before radiographs are ordered
- consider intracranial trauma; rule out skull fracture

Investigations

- CT
  - axial and coronal (specifically request 1.5 mm cuts): for fractures of upper and middle face
  - indicated for significant head trauma, complex facial fractures, orbital floor, panface fractures, pre-operative assessment
- panorex radiograph: shows entire upper and lower jaw; best for isolated mandible fracture but patient must be able to sit
Table 24. Imaging of the Craniofacial Skeleton

</tr>
</tbody>
</table>

**Treatment Goals**

- consultation when indicated (dentistry, ophthalmology)
- re-establish normal occlusion if occlusion is an issue
- pursue normal eye function (extraocular eye movements and vision)
- restore stability of face and appearance

**Complications**

- complications are dependent on the surgery and injury. Not all complications apply to all situations
- diplopia/enophthalmos/blindness
- intracranial pathology such as CSF leak, bleeding and SIADH (secondary to trauma, not the surgery itself)
- sinusitis
- functional abnormalities (i.e. malocclusion)
- infection – extremely rare
- poor cosmesis; need for 2nd surgery

---

**Mandibular Fractures**

- always two points of injury since it is a ring structure (includes fractures and dislocations)
- commonly at sites of weakness (condylar neck, angle of mandible, region of 3rd molar or canine tooth)

**Etiology**

- anterior force: bilateral fractures
- lateral force: ipsilateral subcondylar and contralateral angle or body fracture
- note: classified as open if fracture into tooth bearing area (alveolus)

**Clinical Features**

- pain, swelling, difficulty opening mouth (“trismus”)
- malocclusion, asymmetry of dental arch
- damaged, loose, or lost teeth
- palpable “step” along mandible
- numbness in V3 distribution
- intra-oral lacerations or hematoma (sublingual)
- chin deviating toward side of a fractured condyle

**Classification**

</tbody>
</table>

*Most common mandibular fracture type
Treatment
• maxillary and mandibular arch bars wired together (intramaxillary fixation) or ORIF
• antibiotics to cover against *S. aureus* and anaerobes

Complications
• malocclusion, malunion
• tooth loss, and possible sensation loss
• TMJ ankylosis

Nasal Fractures

Etiology
• lateral force ➔ more common, good prognosis
• anterior force ➔ can produce more serious injuries
• most common facial fracture

Clinical Features
• epistaxis/hemorrhage, deviation/flattening of nose, swelling, periorbital ecchymosis, tenderness over nasal dorsum, crepitus, septal hematoma, respiratory obstruction, subconjunctival hemorrhage
• depression and splaying of nasal bones causing a saddle deformity
• important to clinically assess for naso-orbital ethmoid fractures

Treatment
• treated for airway or cosmetic issues
• closed reduction with Asch or Walsham forceps under anesthesia, pack nostrils with petroleum or non-adhesive gauze packing, nasal splint for 7 d
• best reduction immediately (<6 h) or when swelling subsides (5-7 d)
• rhinoplasty may be necessary later for residual deformity (30%)

Naso-Orbital Ethmoid Fractures

Etiology
• fractures of the nasal and ethmoid bones of the medial orbit
• problematic and may lead to change in facial appearance
• Markowitz-Manson classification:
  ▪ Type 1: Single, central fragment, medial canthal ligament intact
  ▪ Type 2: Comminuted central fragment, medial canthal ligament intact
  ▪ Type 3: Severe comminution of central fragment and disrupted medial canthal ligament

Clinical Presentation
• telecanthus defined as increased intercanthal distance secondary to medial canthal ligament disruption
• orbital rim step-off

Treatment
• surgical repair to restore intercanthal distance (reverse telecanthus), nasal projection and orbital anatomy

Always drain septal hematomas as this is a cause of septal necrosis with perforation (saddle nose deformity)
Zygomatic Fractures

- Classification
  1. Fracture restricted to zygomatic arch
  2. Depressed fracture of zygomatic complex (zygoma)
  3. Unstable fracture of zygomatic complex (tetrapod fracture) – separations occur at maxilla, frontal bone, temporal bone and orbital rim

Clinical Features
- Flattening of malar prominence (view from above)
- Pain over fractures on palpation
- Numbness in V2 distribution (infraorbital and superior dental nerves)
- Palpable step deformity in bony orbital rim (especially inferiorly)
- Often associated with fractures of the orbital floor
- Ipsilateral epistaxis; trismus

Treatment
- If undisplaced, stable and no symptoms, then soft diet; no treatment necessary
- Ophthalmologic evaluation if suspected globe injury
- Undisplaced zygomatic arch fractures can be elevated using Gillies approach: leverage on the anterior part of the zygomatic arch via a temporal incision; stabilization often unnecessary
- ORIF for displaced or unstable fractures of zygomatic complex

Orbital Floor Fractures

- See Ophthalmology, OP43

Definition
- Fracture of floor of orbit ± intact infraorbital rim
- May be associated with nasoethmoid fracture

Etiology
- Blunt force to eyeball → sudden increase in intra-orbital pressure (e.g. baseball or fist)

Clinical Features
- Check visual fields and acuity for injury to globe
- Periorbital edema and bruising, subconjunctival hemorrhage
- Ptosis, exophthalmos, exorbitism, or enophthalmos
- Orbital rim step-offs with possible infraorbital nerve anesthesia
- Vertical dystopia (abnormal displacement of the entire orbital cone in the vertical plane); diplopia looking up or down (entrapment of inferior rectus), limited EOM
- Orbital entrapment
  - Clinical diagnosis that is a surgical emergency
  - Diplopia with vertical gaze; limited EOM
  - Severe pain or nausea and vomiting with upward globe movement
  - Requires urgent ophthalmologic evaluation and surgical repair

Investigations
- CT (diagnostic): axial and coronal views
- Diagnostic manoeuvre for entrapment is forced duction test (pulling on inferior rectus muscle with forceps to ensure full ROM) under anesthesia in the OR

Treatment
- Surgical repair indicated if: Urgent repair for entrapment, floor defect >1 cm, any size defect with enophthalmos or persistent diplopia (>10 d)
- Reconstruction of orbital floor with bone graft or alloplastic material
- Ophthalmologic evaluation suggested

Complications
- Persistent diplopia
- Enophthalmos

Superior Orbital Fissure Syndrome
- Fracture of SOF causing ptosis, proptosis, anesthesia in V1 distribution, and painful ophthalmoplegia (paralysis of CN III, IV, VI)
- Uncommon complication seen in Le Fort II and III fractures (1/130)
- Recovery time reported as 4.8-23 wk following operative reduction of fractures

Orbital Apex Syndrome
- Fracture through optic canal with involvement of CN II at apex of orbit
- Symptoms are the same as SOF syndrome plus vision loss
- Treatment is urgent decompression of fracture in optic canal (posterior craniotomy for decompression) or steroids
Breast Surgery

Breast Reconstruction

• important consideration in breast cancer treatment
• two basic methods: implants (1-stage or 2-stage) or autologous tissue
• may also require breast balancing procedure and nipple areola reconstruction

Pre-Reconstruction Considerations

• radiation: treatment before and after mastectomy is a relative contraindication to alloplastic reconstruction
• recipient tissue: skin sparing mastectomy allows for the use of implants without tissue expanders
• donor tissue: limited availability of suitable donor tissue (lack of tissue, scar, previous surgery that interferes with blood supply) may prevent the use of autologous tissue reconstruction
• timing (immediate vs. delayed)
• contralateral breast: may not be possible to reconstruct a breast of the same size or shape as the contralateral breast. Breast reduction or mastopexy may be considered in opposite breast (see Table 28)
• other considerations: patient’s comorbidities, prognosis, body weight, characteristics of chest wall and patient’s attitude

Table 27. Options for Breast Reconstruction

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Definition</th>
<th>Surgical Details</th>
<th>Other Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alloplastic</td>
<td>Use of synthetic material (silicone or saline implants)</td>
<td>With expanders (2 stages): Use tissue expanders before replacement with implants to facilitate breast ptosis Without expanders (1 stage): In skin-sparing mastectomy, enough skin is available for immediate placement of implant. The limiting factor, however, is the muscle as the implant must fit under the pectoralis (may require acellular dermal matrix if implant size and muscle size is a mismatch)</td>
<td>Complications: capsular contraction (foreign body reaction to implants), rupture or leakage of implant, increased risk of infection, 35% revision rate over 5 yr</td>
</tr>
<tr>
<td>(Implant based)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Autologous Tissue</td>
<td>Use of patient’s own tissue</td>
<td>Many flap options: DIEP, TRAM, latissimus dorsi, SIEA, SGAP, and IGAP</td>
<td>Offers natural consistency</td>
</tr>
<tr>
<td>Nipple Areola</td>
<td>Final stage of breast reconstruction</td>
<td>Local vs. distant flap/graft: 1. Local: fish tail, skate, top hate, double opposing etc.; these flaps allow simultaneous nipple and areola reconstruction 2. Distant: opposite nipple, earlobe, abdominal skin, costal cartilage, labia</td>
<td>Usually performed 3 mo post-reconstruction</td>
</tr>
</tbody>
</table>

Breast Tissue Expanders

• types: textured vs. smooth, both with integrated port
• placement: sub-pectoral, total submuscular (pectoral/serratus)
• size: depends on contralateral breast and desired size
  * generally over-expanded to facilitate ptosis
• timing of expansion: begins when wound fully healed (usually 2 wk post-operative), and tissue expanders are inflated weekly or bi-weekly until complete (up to 3 mo); expanders are exchanged for implants after another 3 mo for consolidation of expanded skin

Arterial blood supply to the breast

• internal thoracic*
• external thoracic*
• lateral thoracic
  * thoracoacromial
  * intercostals
  * thoracodorsal
• also provide arterial blood supply to nipple-areola complex

Figure 37. Augmentation mammoplasty: incision lines and implant placement

Patients may require a balancing procedure on contralateral side

Nipple innervation is T4
Breast Reduction

- reduction mammoplasty performed for relief of physical symptoms (e.g. shoulder groove, neck pain, back pain, shoulder pain, mastodynia)
- key steps of procedure include preoperative landmarks, design of pedicle, nipple preservation, tissue resection, breast reshaping, setting nipple at aesthetic landmark, and tension free closure
  - incisions: circular around the areola, vertical from areola incision to infra-mammary fold, along the natural infra-mammary fold (this incision is for a wise pattern reduction, although many other types exist)
  - removal of fat, breast tissue, and excess skin
  - need to move nipple and areola complex to higher position
- complications: infection, hemorrhage, decreased nipple sensation, inability to breast feed, breast/nipple asymmetry, nipple loss (partial or complete), skin loss/necrosis, fat necrosis

Public Health Context

- see Ethical, Legal, and Organizational Medicine, ELOAM2 Overview of Canadian Healthcare System for the organization of health care in Canada including the legal foundation and historical context

Definitions

- population health
  - health of the population as measured by health status indicators (e.g. life expectancy, low birth weight rates)
  - influenced by: physical, biological, social, environmental, and economic factors; personal health behaviours; health care services
  - refers to the prevailing or desired level of health in the population of a specific country/region/subset of population
  - considered to be more complex than the aggregate health status of individuals within a population

- public health
  - organized collective efforts of society to protect, promote, and restore the health of the public and prevent illness, injury, and premature death
  - refers to the practices, programs, policies, institutions, and disciplines required to achieve the desired state of population health

- epidemiology
  - study of the distribution and determinants of health-related states or events in a specified populations
  - application of this study to the control of health problems

- public health and preventive medicine (formerly called community medicine)
  - the postgraduate study of health and disease in the population or a specified community
  - five-year Royal College specialty training
  - goal: to identify and address health problems and evaluate the extent to which health services and others address these issues (see http://www.royalcollege.ca for more information)

Public Health Services in Canada

Mission: to promote and protect the health of Canadians, and reduce health inequities through leadership, partnership, innovation, and action in public health

- local public health units and services within regional health authorities (in most provinces except Ontario, where local public health units are either autonomous or within local government) provide programs and activities for health protection, promotion, and disease prevention at local and regional levels
- catchment-area populations range from hundreds to thousands of people, covering areas of 15 km² to 1.5 million km²
- the “core functions” of public health include six essential activities:
  1. health protection: ensure safe water, air, and food; advise on food and drug safety regulations; maintain regulatory framework for control of infectious diseases and protection from environmental threats
  2. health surveillance: using routinely collected health data to monitor and predict health events or determinants
  3. disease and injury prevention: reduce risk of infectious disease by investigation, partner notification, and development of preventative and control measures such as immunization programs; reduce preventable illness and injuries by promoting safe, healthy lifestyles
  4. population health assessment: understand the health of communities/specific population to produce better policies and services
  5. health promotion: maintain and improve health through public policy, community-based interventions, active public participation, and advocacy
  6. emergency preparedness and response: planning for natural (e.g. floods, earthquakes) and man-made (e.g. radioactive substances) threats

Preparation for the LMCC

The AFMC Primer on Population Health is the core text for the LMCC and is available as an online resource on the AFMC website (http://phprimer.afmc.ca)

For the LMCC exam, it is recommended that you also read Chapter 15 in Shah CP. Public Health and preventive medicine in Canada, 5th ed. Toronto: Elsevier, 2003

Historical Perspective

Over the last century, Public Health has evolved through three main epidemiological phases:

- Infectious diseases: controlled in the more developed world but an issue in less developed countries (e.g. polio, malaria)
- Chronic diseases: chronic diseases and other noncommunicable conditions have increased morbidity and mortality (e.g. heart disease and cancer due to risk factors and/or exposures)
- Re-emerging infectious diseases: new or re-emerging infections emerge due to unfamiliar or new pathogens, inefficient or inappropriate antibiotic use, travel, and global warming (e.g. HIV, drug resistant TB and malaria)

CPhO of Canada

- Responsible for the PHAC and reports to the Minister of Health
- As the federal government’s lead public health professional, provides advice to the Minister of Health and Government of Canada on health issues
- Collaborates with other governments, jurisdictions, agencies, organizations, and countries on health matters
- Communicates public health information to health professionals, stakeholders, and the public
- In an emergency, such as an outbreak or natural disaster, provides direction to PHAC staff, including medical professionals, scientists, and epidemiologists, as they plan and respond to the emergency

### Legislation and Public Health in Canada

#### Table 1. Legislation and Public Health in Canada

<table>
<thead>
<tr>
<th>Federal</th>
<th>Provincial</th>
<th>Municipal (Ontario)</th>
</tr>
</thead>
</table>
| • Health Canada  
  • Provides health services to First Nations, Aboriginal peoples, the Canadian military, and veterans  
  • Approves new drugs and medical devices  
  • Canadian Food Inspection Agency  
  • Monitors food products  
  • Deals with animal-related infections  
  • Regulates food labeling  
  • Public Health Agency of Canada (main Government of Canada agency responsible for public health)  
  • An independent body created to strengthen public health capacity  
  • Focuses on preventing chronic diseases, preventing injuries, and responding to public health emergencies and infectious disease outbreaks  
  • Oversees immigration screening, protects Canadian borders (e.g. airport health inspection)  
  • Liases with the World Health Organization (WHO) on global health issues | • Legislation is in the form of Acts and Regulations  
  • Each province has its own Public Health Act or equivalent (e.g. the Health Protection and Promotion Act in Ontario)  
  • Designates the creation of geographic areas for the provision of public health services  
  • Gives powers to the Chief Medical Officer of Health to control public health hazards  
  • Specifies infectious diseases to be reported to public health units by physicians, laboratories, and hospitals (see Appendix, PH25)  
  • Has the ability to mandate programs that address public health issues, environmental health, and chronic disease prevention | • Local boards of health deliver programs mandated by provincial and municipal or regional legislation  
  • Boards of health are responsible for the delivery of most public health services, such as:  
  • Infectious disease control, including the follow-up of reported diseases and management of outbreaks  
  • Inspection of food premises including those in hospitals, nursing homes, and restaurants  
  • Family health services including pre-conception, preschool, school-aged, and adult health programs  
  • Tobacco control legislation enforcement  
  • Assessment and management of local environmental health risks  
  • Collection and dissemination of local health status reports  
  • Public dental health services to children  
  • By-laws may be approved by municipal governments to facilitate public health issues |

### Concepts of Health

- **wellness**: state of dynamic physical, mental, social, and spiritual well-being that enables a person to achieve full potential and have an enjoyable life  
- **disease**: abnormal, medically-defined changes in the structure or function of the human body  
- **illness**: an individual’s experience or subjective perception of a lack of physical or mental well-being and consequent inability to function normally in social roles  
- **illness behaviour**: an individual’s actions in response to their illness, including whether they seek health care and whether they comply with the subsequent recommendations  
- **sickness**: socially and culturally held conceptions of health conditions that may influence how the patient reacts  
- **impairment**: any loss or abnormality of psychological, physiological, or anatomical structure or function  
- **disability**: any restriction or lack of ability to perform an activity within the range considered normal for a human being  
- **handicap**: the disadvantage for an individual arising due to impairment and disability  
  - limits or prevents the fulfillment of an individual’s normal role as determined by society and depends on age, sex, social, and cultural factors  
  - changes the individual’s relationship with the physical and social environment  
- **health equity**: when all people have “the opportunity to attain their full health potential” and no one is “disadvantaged from achieving this potential because of their social position or other socially determined circumstance.” Differs from health equality. Health inequities are those which are considered unjust and/or avoidable  
- **health equality**: defined as where populations have equal or similar health status. Health inequalities are systematic differences in health status that occur among population groups

### Determinants of Health

- **1974**: the Honourable Marc Lalonde, federal Minister of Health, presented the health field concept entitled *A New Perspective on the Health of Canadians* which included four areas that interact to determine health: human biology, environment, lifestyle, and health care. This concept has been expanded to include numerous determinants of health

**Definitions of Health**

- First multidimensional definition of health, as defined by the WHO in 1948: “state of complete physical, mental and social well-being and not merely the absence of disease or infirmity”  
- WHO updated the definition (socio-ecological definition) of health in 1986: “The ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not the objective of living. Health is a positive concept emphasizing social and personal resources, as well as physical capacities” (Ottawa Charter for Health Promotion)  
- Other definitions of health have since been proposed that incorporate other dimensions of health (e.g. “Health is a social, economic, and political issue and above all a fundamental human right” – The People’s Charter for Health)

**Determinants of Health**

- Income and social status  
- Social support networks  
- Education and literacy  
- Employment and working conditions  
- Social and work environments  
- Physical environment  
- Personal health practices and coping skills  
- Healthy child development  
- Biology, genetics, and epigenetics  
- Health services  
- Gender  
- Culture

Social Determinants: Indigenous People’s Health in Canada

- Colonization: subjugation of Indigenous peoples by the Europeans, leading to the loss of lands, cultural practices, and self-government
- Residential schools: placement of children from Indigenous groups in church-run, government-funded schools for the purpose of assimilation, resulting in loss of identity, alienation, and abuse, with long-lasting consequences of higher rates of addictions, abusive relationships, and suicide
- Treaties and Land Claims: inadequate services for those living on reserves leading to poverty and poor quality infrastructure, reflected in disproportionate burden of infectious diseases (e.g. pertussis, Chlamydia, hepatitis, shigellosis)
- Traditional Approach to Healing: restoring balance in the four realms of spiritual, emotional, mental and physical health of a person acting as an individual, as well as a member of a family, community and nation
- Ideas represented by medicine wheel of First Nations peoples, the Learning Blanket of Inuit peoples, and the Metis tree model of Holistic Lifelong Learning
- Contrast to Western medicine focus of treating illness, leading to challenges for practitioners of Western medicine to meet Aboriginal patients’ needs
- National Aboriginal Health Organization (NAHO) offers 8 guidelines on practicing culturally safe health care for Aboriginal patients including need to allow Aboriginal patients access to ceremony, song, and prayer; the need for information and for family support; guidelines for the appropriate disposal of body parts and for handling death

New Immigrants to Canada

- Mandatory medical exams on entry to Canada by a designated medical practitioner:
  - Complete medical examination for all persons of all ages
  - Chest x-ray and report for persons 11 yr of age and over
  - Urinalysis for persons 5 yr of age and over
  - Syphilis serology for persons 15 yr of age and over
  - HIV testing for applicants 15 yr of age and over, as well as for those children who have received blood or blood products, have a known HIV-positive mother, or have an identified risk. An ELISA HIV screening test should be done for HIV 1 and HIV 2
  - Serum creatinine if the applicant has hypertension (resting blood pressure greater than 140/90 mmHg), a history of treated hypertension, DM, autoimmune disorder, persistent proteinuria, or kidney disorder

</table>

Note: this chart delineates the major challenges faced by each group, but the issues listed are not unique to each population.

Disease Prevention

Natural History of Disease
- course of a disease from onset to resolution
  1. pathological onset
  2. presymptomatic stage: from onset to first appearance of symptoms/signs
  3. clinically manifest disease: may regress spontaneously, be subject to remissions and relapses, or progress to death

Disease Prevention Strategies
- measures aimed at preventing the occurrence, interrupting through early detection and treatment, or slowing the progression of disease/mitigating the sequelae

Table 3. Levels of Disease Prevention

<table>
<thead>
<tr>
<th>Level of Prevention</th>
<th>Goal</th>
<th>Sample Strategies</th>

<td>Mammography Routine Pap smears</td>
</tr>
<tr>
<td>Tertiary</td>
<td>Treatment and rehabilitation of disease to prevent progression and permanent disability</td>
<td>DM monitoring with HbA1c, eye exams, foot exams Medication</td>
</tr>
</tbody>
</table>

Screening (Secondary Prevention)
- presumptive identification (not diagnosis) of unrecognized disease or defect by the application of tests, examinations, or other procedures which can be applied rapidly

- types of screening
  - mass screening: screening all members of a population for a disease (e.g. phenylketonuria (PKU) and hypothyroidism in all newborns)
  - selective screening: screening of a specific subgroup of the population at risk for a disease (e.g. mammography in women >50 yr old)
  - multiphasic screening: the use of many measurements and investigations to look for many disease entities (e.g. periodic health exam)

- bias in screening
  - lead-time: time between early diagnosis with screening, and when diagnosis would have been made without screening
  - lead-time bias: over-estimation of survival when the estimate is made from the time of screening, instead of the later time when the disease would have been diagnosed without screening
  - length-time bias: overestimation of the survival time due to the sampling of prevalent as opposed to incident cases
    - selection of prevalent cases will favour the over-inclusion of longer-living cases rather than newly-diagnosed incident cases, some of whom may have short survival times
Figure 2. Lead-time bias

Healthy Public Policy
- characterized by an explicit concern for health and equity in all areas of policy and by an accountability for health impact
- main aim: to create a supportive environment to enable people to lead healthy lives, thereby making healthy choices easier for citizens
- government sectors must take into account health as an essential factor when formulating policy and should be accountable for the health consequences of their policy decisions
- methods
  - fiscal: imposing additional costs (e.g. taxes on tobacco and alcohol)
  - legislative: implementing legal deterrents (e.g. smoking bans, legal alcohol drinking age)
  - social: improving health beyond providing universally funded health care (e.g. providing affordable housing)

Source: International Conference on Health Promotion, Adelaide, South Australia (1998)

Behaviour Change
- health education serves to
  - increase knowledge and skills
  - encourage positive behaviour changes and discourage unhealthy choices
- health education is an important component of eliciting behaviour change
- behaviour is a result of three factors
  1. predisposing factors: knowledge, attitude, beliefs, values, intentions
  2. enabling factors: skills, supports
  3. reinforcing factors: health care professionals and the social context of family and community

Health Belief Model (1975)
- behaviours undertaken by individuals in order to remain healthy are a function of a set of interacting beliefs
- beliefs include an individual’s perception of his or her susceptibility to a disease, the severity of the disease, and the benefits and costs of health-related actions
- beliefs are modified by socio-demographic and psychosocial variables

Example of Harm Reduction Strategy
Summary of Findings from the Evaluation of a Pilot Medically Supervised Safer Injection Facility
CMAJ 2006;175:1399-1404
Background: This study discusses the outcomes among a population of illicit injection drug users (IDUs) after initiating a supervised safe injecting facility in Vancouver, September 2003. Legal exemption by the Canadian government was granted such that an evaluation of its results be conducted over a 3 yr period.
Study Population: IDUs of the Vancouver area were allowed to inject previously obtained illicit drugs under the supervision of nurses and physicians. IDUs were offered addiction counseling and supports for appropriate community resources.
A random sample of 670 IDUs was recruited and monitored from Dec 2003-July 2004.
Results: Characteristics of IDUs who used the safe injecting facility included age <30 yr, history of public drug use, homelessness, daily heroin and/or cocaine injection, and recent history of overdose. Mean measures of public order problems were taken 6 wk before and 12 wk after initiation of the safer injection facility. It was found that the mean number of IDUs injecting daily in public, along with the mean number of publically discarded syringes were reduced by approximately half.
Conclusions: Overall it has been found that the safer injecting facility in Vancouver has been successful in attracting IDUs at increased risk of HIV, overdose, and public injection of substances. This has resulted in lower incidences of public drug use, publicly discarded syringes and sharing of needles. Other studies associated with this one have demonstrated that there has been no increase in the drug dealing, drug related crimes, or rates of new IDUs in the area surrounding the safer injecting facility.
- individuals must believe that the action will have positive consequences
- individuals must be in a state of readiness
- behaviour can be stimulated by cues to action, which are specific events that can encourage preventive health decisions and actions (e.g. physician recommendation, public advertising)

- **Stages of Change Model**
  - provides a framework in which the Health Belief Model is applied to facilitating behaviour change (e.g. quitting smoking)

  ![Figure 3. Stages of change model](source)

  **Risk Reduction Strategies**
  - **risk reduction**: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
  - **harm reduction**: tolerance of some degree of risk behaviour, while aiming to minimize the adverse outcomes associated with these behaviours (e.g. needle exchange programs)

### Measurements of Health and Disease in a Population

#### MEASURES OF DISEASE RATES

- **Incidence Rate**
  - number of new cases in a population over a defined period of time

- **Prevalence**
  - *total number* of cases in a population over a defined period of time
  - *two forms of prevalence*
    - **point prevalence**: attempts to measure the frequency of all disease at a specific point in time, therefore knowledge of the time of onset of disease is not required
    - **period prevalence**: measure constructed from prevalence at a point in time, plus new cases and recurrences over a defined period of time
  - depends on **incidence rate** and disease duration from onset to termination (cure or death)
  - favours the inclusion of chronic over acute cases and may be used to present a biased picture of the disease
  - prevalence studies are cross-sectional and cannot be used for causal inferences
  - prevalence figures are useful for determining the extent of a disease and can aid in the rational planning of facilities and services

- **Age Standardized Rate**
  - adjustment of the crude rate of a health-related event using a “standard” population
  - standard population is one with a known number of persons in each age and sex group
  - standardization prevents bias which could be made by comparing crude rates from two dissimilar populations (e.g. crude death rates over a number of decades are not comparable as the population age distribution has changed with time)

#### MEASURES OF MORTALITY

- **Life Expectancy**
  - the expected number of years that an individual will live based on standardized death rates for the population
  - usually qualified by country, gender, and age
Crude Death Rate
- mortality rate from all causes of death per 1,000 in the population

Infant Mortality Rate (IMR)
- number of deaths among children under 1 yr of age reported during a given time period divided by the number of live births reported during the same time period and expressed per 1,000 live births per year

Maternal Mortality Rate (MMR)
- number of deaths of women during pregnancy and due to puerperal causes per 100,000 live births per year

Standardized Mortality Rate (SMR)
- the ratio of the observed (actual) number of deaths to the expected number of deaths for a group (e.g. age, race, gender, etc.)
- useful for comparing populations that are significantly different in some aspect (e.g. the causes of death in more and less developed countries)

MEASURES OF DISEASE BURDEN

Potential Years of Life Lost (PYLL)
- calculated for a population using the difference between the actual age at death and a standard/expected age at death
- increased weighting of mortality at a younger age

Disability Adjusted Life Year (DALY)
- quantitative indicator of the burden of diseases that reflects the total amount of disability-free life years lost
- includes loss from premature mortality and loss due to a degree of disability over a specific period of time; these disabilities can be physical or mental

Quality Adjusted Life Year (QALY)
- a value from 0 to 1 assigned to a year of life based on perceived quality of life; a yr in "perfect" health is considered equal to 1 QALY, the value of a year in ill health would be lowered based on the burden of disease
- it is possible to have "states worse than death" for example QALY <0 for extremely serious conditions

For additional rate calculations see Outbreak of Infectious Diseases, PH19

Consult the Public Health Agency of Canada for examples and latest statistics

Epidemiology

Population
- a collection of individuals who share a common trait (most commonly applied to a geographic area but it could be another factor such as ethnic group)

Sample
- a selection of individuals from a population or set of observations
- types
  - random: all are equally likely to be selected
  - systematic: an algorithm is used to select a subset
  - stratified: separate representations of more than one subgroup
  - cluster: grouped in space/time to reduce costs
  - convenience: non-random inclusion, usually volunteers

Sample Size
- sample size contributes to the statistical precision of the observed estimate
- increasing the sample size decreases the probability of type I and type II errors (see Data Analysis, PH14)
Bias
• non-random error leading to a deviation of inferences or results from the truth
• any trend in the collection, analysis, interpretation, publication, or review of data that can lead to conclusions that are systematically different from the truth
  • sampling bias: occurs with the selection of a sample that does not truly represent the population
  • sampling procedures should be chosen to prevent or minimize bias
  • measurement bias: systematic error arising from inaccurate measurements of subjects
  • recall bias: when individuals with a disease are more prone to recalling or believing they were exposed to a possible causal factor than those who are free of disease

Confounder
• a variable that is related to both the exposure and outcome but is not measured or is not distributed equally between groups
• distorts the apparent effect of an exposure or risk because it may not be possible to separate/control for the contribution of a single causal factor to an effect (e.g. late maternal age could be a confounder in an investigation of birth order >4 and risk of developing Trisomy 21)

Interpreting Test Results

<table>
<thead>
<tr>
<th>Disease</th>
<th>Present</th>
<th>Negative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test Result</td>
<td>Positive</td>
<td>TP</td>
</tr>
<tr>
<td></td>
<td>Negative</td>
<td>FN</td>
</tr>
</tbody>
</table>

Sensitivity = TP/(TP+FN)
Specificity = TN/(TN+FP)

Likelihood Ratio (LR)
• Likelihood that a given test result would be expected in a patient with disease compared with the likelihood that the same result would be expected in a patient without disease
• LR+ indicates how much the probability of disease increases if the test is positive
• LR- indicates how much the probability of disease decreases if the test is negative

LR+ = Sensitivity = [TP/(TP+FN)]
1 - Specificity = [FP/(TN+FP)]

LR- = 1 - Sensitivity = [FN/(TP+FN)]
Specificity = [TN/(TN+FP)]

Positive Predictive Value (PPV)
• Proportion of people with a positive test who have the disease

PPV = TP / (TP + FP)

Negative Predictive Value (NPV)
• Proportion of people with a negative test who are free of disease

NPV = TN / (TN + FN)

Advanced Neoplasia

<table>
<thead>
<tr>
<th>Test Result</th>
<th>Present</th>
<th>Negative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>68</td>
<td>147</td>
</tr>
<tr>
<td>Negative</td>
<td>216</td>
<td>2234</td>
</tr>
<tr>
<td>Total</td>
<td>284</td>
<td>2381</td>
</tr>
</tbody>
</table>

Sensitivity = 68/284 = 23.9%
Specificity = 2234/2381 = 93.8%

LR+ = 0.239
LR- = 1 - 0.938 = 0.81
PPV = 68 / (68 + 147) = 31.6%
NPV = 2234 / (2234 + 216) = 91.2%

Figure 5. Interpreting test results: Practical example using FOBT testing in advanced colon cancer

SPIN: use a Specific test to rule IN a hypothesis. Note that specific tests have very few false positives. If you get a positive test, it is likely a true positive

SNOUT: use a Sensitive test to rule OUT a hypothesis. Note that sensitive tests have very few false negatives. If you get a negative test, it is likely a true negative

Figure 4a. Hypothetical population
Figure 4b. Results of diagnostic test on hypothetical population
Figure 4c. Sensitivity of test (e.g. 24/30 = 80% sensitive)
Figure 4d. Specificity of test (e.g. 56/70 = 80% specific)

Source: Loong TW. Understanding sensitivity and specificity with the right side of the brain. BMJ 2003;327:716-719
Sensitivity
- proportion of people with disease who are correctly identified by having a positive test

Specificity
- proportion of people without disease who are correctly identified by having a negative test

Pre-Test Probability
- an estimate of the likelihood a particular patient has a given disease based on known factors

Post-Test Probability
- a revision of the probability of disease after a patient has been interviewed and examined
- calculation process can be more explicit using results from epidemiologic studies, knowledge of the accuracy of tests, and Bayes' theorem
- the post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
- after each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

Effectiveness of Interventions

Effectiveness, Efficacy, Efficiency
- three measurements indicating the relative value (beneficial effects vs. harmful effects) of an intervention
  - efficacy: the extent to which a specific intervention produces a beneficial result under ideal conditions
    - ideally, based on the results of a randomized control trial (the theoretical impact)
  - effectiveness: measures the benefit of an intervention under usual conditions of clinical care
    - considers both the efficacy of an intervention and its actual impact on the real world, taking into account access to the intervention, whether it is offered to those who can benefit from it, its proper administration, acceptance of intervention, and degree of adherence to intervention
  - efficiency: a measure of economy of an intervention with known effectiveness
    - considers the optimal use of resources (e.g. money, time, personnel, equipment, etc.)

\[
\begin{array}{ccc}
\text{Disease (e.g. lung CA)} & \\
\text{Exposure (e.g. smoking)} & \text{Present} & \text{Absent} & \text{Total} \\
\text{Present} & A & B & A + B \\
\text{Absent} & C & D & C + D \\
\text{Total} & A + C & B + D & A + B + C + D \\
\end{array}
\]

Case-Control Study
\[
\text{odds ratio (OR)*} = \frac{A \times C}{B \times D} = \frac{A \times D}{B \times C}
\]

Cohort Study
\[
\text{incidence rate of health outcome in exposed} = \frac{C}{C + D} = \text{incidence rate of health outcome in non-exposed}
\]
\[
\text{relative risk (RR)**} = \frac{A}{A + B} + \frac{C}{C + D}
\]
\[
\text{attributable risk (AR)***} = \frac{A}{A + B} + \frac{C}{C + D}
\]

*Ratio of the odds in favour of the health outcome among the exposed to the odds in favour among the unexposed
**Ratio of the risk of a health outcome among exposed to the risk among the unexposed
***Rate of health outcome in exposed individuals that can be attributed to the exposure

Figure 7. Measures of effect by study type

Figure 6. Fagan’s likelihood ratio nomogram: Practical example using PSA levels to calculate post-test probability of prostate cancer

©Naveen Devasagayam 2016

Equations to Assess Effectiveness
- CER = control group event rate
- EER = experimental group event rate
- RR = EER/CER
- AR = CER – EER
- NNT = 1/ARR

Beware
Do not be swayed by a large RR, as it may appear to be large if event rate is small to begin with. In these cases AR is more important (e.g. a drug which lowers an event which occurs in 0.1% of a population to 0.05% can boast a RR of 50%, and yet the AR is only 0.05%, which is not nearly as impressive)
**Number Needed to Treat (NNT)**
- number of patients who need to be treated to achieve one additional favourable outcome
- only one of many factors that should be taken into account in clinical or health system decision making (e.g. must take into account cost, ease, feasibility of intervention)
  - a condition with death as a potential outcome can have a higher NNT (and be acceptable), as compared to an intervention to prevent an outcome with low morbidity, in which a low NNT would be necessary

**Number Needed to Harm (NNH)**
- number of patients who, if they received the experimental treatment, would lead to one additional patient being harmed, compared with patients who received the control treatment

**Adherence (formerly compliance)**
- degree to which a patient follows a treatment plan

**Coverage**
- extent to which the services rendered cover the potential need for these services in a community

---

**Types of Study Design**

### Qualitative vs. Quantitative

<table>
<thead>
<tr>
<th>Qualitative</th>
<th>Quantitative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates hypothesis (Why? What does it mean?)</td>
<td>Tests hypothesis (What? How much/many?)</td>
</tr>
<tr>
<td>Inductive (specific to general): “bottom up” Observation → pattern → tentative hypothesis → theory</td>
<td>Deductive (general to specific): “top down” Theory → hypothesis → observation → confirmation</td>
</tr>
<tr>
<td>Sampling approach to obtain representative coverage of ideas or concepts</td>
<td>Sampling approach to obtain representative coverage of people in the population</td>
</tr>
<tr>
<td>Narrative: rich, contextual, and detailed information from a small number of participants</td>
<td>Numeric: frequency, severity, and associations from a large number of participants</td>
</tr>
</tbody>
</table>

Source: Adapted from http://phprimer.afmc.ca

---

**Quantitative Research Methods**

![Figure 8. Quantitative study designs](Source: Adapted from http://phprimer.afmc.ca)
Observational Study Designs

- observational studies involve neither the manipulation of the exposure of interest nor randomization of the study subjects
- there are two main subtypes of observational studies: descriptive and analytic studies

Descriptive Studies

- describe the events and rates of disease with respect to person, place and time and to estimate disease frequency and time trends
- first sets of studies and are used to generate an etiologic hypothesis, not test a hypothesis

Analytic Studies

- observational studies used to test a specific hypothesis
- includes ecological studies, cohort studies, case-control studies, and cross-sectional studies

Table 7. Observational Study Designs

<table>
<thead>
<tr>
<th>Type of Study</th>
<th>Ecological</th>
<th>Cross-Sectional</th>
<th>Case-Control</th>
<th>Cohort</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Definition</strong></td>
<td>Units of analysis are populations or groups of people, rather than individuals</td>
<td>Assessment of individuals with respect to presence and absence of exposures and diseases at the same point in time</td>
<td>Samples a group of people who already have a particular outcome (cases) and compares them to a similar sample group without that outcome (controls)</td>
<td>Subjects are sampled and, as a group, classified on the basis of presence or absence of exposure to a particular risk factor</td>
</tr>
<tr>
<td><strong>Subjects</strong></td>
<td>Population (e.g. geographic areas)</td>
<td>Population (sample)</td>
<td>Two study sample populations are compared: cases and controls</td>
<td>One or more cohorts Cohort: group of people with common characteristics (e.g. year of birth) Divided into measured exposed vs. non-exposed groups</td>
</tr>
<tr>
<td><strong>Methods</strong></td>
<td>Descriptions of the average exposure or risk of disease for a population</td>
<td>Collect information from each person at one particular time Tabulate the numbers in groups (e.g. by presence or absence of disease/factor of interest) Make 2 x 2 table and compare groups Estimate prevalence</td>
<td>Ask cases and controls about exposures Select all the cases of a specific disease during a specific time frame Representative of spectrum of clinical disease Select control(s) Represent the general population To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g. age, gender) Association can be concluded between the risk factor and the disease (odds ratio) Estimate incidence</td>
<td>Subjects are followed for a specific period of time to determine development of disease in each exposure group Prospective: measuring from the exposure to the future outcomes – looking forward Retrospective: measuring from outcomes to possible risk factors or protective factors – looking back Collect information on factors from all persons at the beginning of the study Tabulate the number of persons who develop the disease or other measured outcomes of morbidity Provides estimates of incidence, relative risk, attributable risk</td>
</tr>
<tr>
<td><strong>Advantages</strong></td>
<td>Quick, easy to do Uses readily available data Generates hypothesis</td>
<td>Determines association between variables Quick and uses limited resources Surveys with validated questions allows comparison between studies</td>
<td>Used when disease in population is rare (less than 10% of population) due to increased efficiency Less costly and time consuming</td>
<td>Shows an association between a factor and an outcome/several outcomes Stronger evidence for causation</td>
</tr>
<tr>
<td><strong>Disadvantages</strong></td>
<td>Poor generalizability to individual level (not direct assessment of causal relationship) Ecological fallacy: an incorrect inference about individuals in the population</td>
<td>Does not allow for assessment of temporal relationship or causation between variables Recall bias (see Bias, PH9)</td>
<td>Recall bias (see Bias, PH9) Confounding Selection bias for controls Only one outcome can be measured</td>
<td>By itself, cannot establish causation Confounding factors are common as the cohort self-selects the exposure, or unknown/unmeasured factors are associated with the measured exposure Cost and duration of time needed to follow cohort</td>
</tr>
<tr>
<td><strong>Examples</strong></td>
<td>A study looking at the association between smoking rates and lung cancer rates in different countries at the population level without individual data on both factors</td>
<td>A study that examines the distribution of BMI by age in Ontario at a particular point in time</td>
<td>A famous case control study is by Sir Richard Doll who demonstrated the link between tobacco smoking exposure and lung cancer cases at the individual level</td>
<td>A famous cohort study is the Framingham Heart Study, which assessed the long-term cardiovascular risks of diet, exercise, medications such as ASA, etc.</td>
</tr>
</tbody>
</table>
Experimental Study Designs

• not discussed here are non-randomized control trials (e.g. allocation by clinic or other non-random basis – performed when randomization is not possible) and clinical trials (e.g. test treatments or laboratory tests in human subjects)

RANDOMIZED CONTROLLED TRIAL (RCT)

Definition
• subjects are assigned by random allocation to two or more groups, one of which is the control group, the other group(s) receive(s) an experimental intervention

Subjects
• individuals are separated into groups by a random process to ensure as much as possible equal distribution of known and unknown factors except for the experimental exposure (e.g. the treatment)

Methods
• random allocation of individuals into two or more treatment groups through a centralized concealed process
• method of assessment to reduce bias
  ▪ single-blind: subject does not know group assignment (intervention or placebo)
  ▪ double-blind: subject and observer both unaware of group assignment
  ▪ triple-blind: subject, observer, and analyst unaware of group assignment (rarely done)
• one group receives placebo or standard therapy
• one or more groups receive(s) the intervention(s) under study
• the outcome is measured and the groups are compared
• all other conditions are kept the same between groups

Advantages
• “gold standard” of studies, upon which the practice of EBM is founded
• provides the strongest evidence for effectiveness of intervention
• with sufficient sample size and appropriate randomization, threats to validity are minimized
• allows prospective assessment of the effects of intervention while minimizing bias

Disadvantages
• some exposures are not amenable to randomization (e.g. cannot randomize subjects to poverty/wealth or to harmful exposures such as smoking) due to ethical or feasibility concerns
• difficult to randomly allocate groups (e.g. communities, neighbourhoods)
• difficult to study rare events, since RCTs would require extremely large sample sizes
• costly

Summary Study Designs

META-ANALYSIS

Definition
• a form of statistical analysis that combines the results of independent studies addressing a common research hypothesis, as identified through systematic review, into one large study

Subjects
• combination of all the subjects used in original studies

Methods
• selection of relevant studies from the published literature which meet quality criteria
• statistical models used to combine the results of each independent study
• provides a summary statistic of overall results as well as graphic representation of included studies

Advantages
• attempts to overcome the problem of reduced power due to small sample sizes of individual studies
• ability to control for inter-study variation

Disadvantages
• sources of bias may not be controlled for
• reliance on published studies may increase the potential conclusion of an effect as it can be difficult to publish studies that show no significant results (publication bias)
• the decision to include/reject a particular study is subjective
Methods of Analysis

Distributions

- distribution describes the probability of events
- normal (Gaussian) or non-normal (skewed, bimodal, etc.)
- characteristics of the normal distribution
  - mean = median = mode
  - 67% of observations fall within one standard deviation of the mean
  - 95% of observations fall within two standard deviations of the mean
- measures of central tendency
  - mean: sum of all observations divided by total number of variables
  - median: value at the 50th percentile, a better reflection of the central tendency for a skewed distribution
  - mode: most frequently observed value in a series
- measures of dispersion
  - range: the largest value minus the smallest value
  - variance: a measure of the spread of data
  - standard deviation: the average distance of data points from the mean (the positive square root of variance)
- given the mean and standard deviation of a normal or binomial distribution curve, a description of the entire distribution of data is obtained

Data Analysis

Statistical Hypotheses

- null (H₀)
  - no relationship exists between the two stated variables (i.e. no association between the hypothesized exposure and the outcome)
- alternative (H₁)
  - a relationship does exist between the two stated variables

Type I Error (α Error)

- the null hypothesis is falsely rejected (i.e. concluding an intervention X is effective when it is not, or declaring an observed difference to be real rather than by chance)
- the probability of this error is denoted by the p-value
- studies tend to be designed to minimize this type of error, since a type I error can have larger clinical significance than a type II error

Type II Error (β Error)

- the null hypothesis is falsely accepted (i.e. stating intervention X is not effective when it is, or declaring an observed difference/effect to have occurred by chance when it is present)
- higher level of error is acceptable for most studies
- can also be used to calculate statistical power

Power

- probability of correctly rejecting a null hypothesis when it is in fact false (i.e. the probability of finding a specified difference to be statistically significant at a given p-value)
- power increases with an increase in sample size
- power = 1 – β, and is therefore equal to the probability of a true positive result

Statistical Significance

- the probability that the statistical association found between the variables is due to random chance alone (i.e. that there is no association)
- the preset probability is set sufficiently low that one would act on the result; frequently p=0.05
- when statistical tests result in a probability less than the preset limit, the results are said to be statistically significant (i.e. p<0.05)

Clinical Significance

- measure of clinical usefulness (e.g. 1 mmHg BP reduction may be statistically significant, but may not be clinically significant)
- depends on factors such as cost, availability, patient compliance, and side effects in addition to statistical significance

Trend

- an observed directional relationship that does not meet criteria for statistical significance and thus should be interpreted with caution
Confidence Interval (CI)
- provides a range of values within which the true population result (e.g., the mean) lies
- frequently reported as 95% CI (i.e., one can be 95% certain that the true value is within this data range)
- bounded by the upper and lower confidence limits

Data
- information collected from a sample of a population
- there are 2 overall classes of data listed with examples
  - discrete
    - categorical (e.g., gender, marital status)
    - ordinal (e.g., low, medium, high)
  - continuous (e.g., serum cholesterol, hemoglobin, age)

Accuracy
- how closely a measurement approaches the true value

Reliability
- how consistent a measurement is when performed by different observers under the same conditions or by the same observer under different conditions

Validity
- extent to which a measurement approaches what it is designed to measure
- determined by the accuracy and reliability of a test

Internal Validity
- degree to which the findings of the sample truly represent the findings in the study population
- dependent on the precision and accuracy

External Validity (i.e., Generalizability)
- degree to which the results of the study can be generalized to other situations or populations

Common Statistical Tests

Table 8. Statistical Tests

<table>
<thead>
<tr>
<th>What are you trying to show?</th>
<th>Z-Test (known as t-test for samples &lt;30)</th>
<th>Analysis of Variance (ANOVA)</th>
<th>Chi-Squared Test ($\chi^2$)</th>
<th>Linear Regression</th>
<th>Logistic Regression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare the mean values of an outcome variable between two groups (e.g., difference in average BP between men and women)</td>
<td>Compare the mean values of an outcome variable between two or more groups (e.g., difference in average BP between persons in three towns)</td>
<td>Test the correspondence between a theoretical frequency distribution and an observed frequency distribution (e.g., if one sample of 20 patients is 30% hypertensive and another comparison group of 25 patients is 60% hypertensive, a chi-squared test determines if this variation is more than expected due to chance alone)</td>
<td>Looks at associations between two or more continuous variables (e.g., age and blood pressure)</td>
<td>Shows how a change in one explanatory variable affects the status (e.g., ill vs. non-ill) of the outcome variable</td>
<td></td>
</tr>
</tbody>

</tr>
</tbody>
</table>

Assumptions

| “Normal” distribution | None | Dependent variable has “normal” distribution Linear relationship between variables | None |

Figure 12. Accuracy vs. reliability

A wider confidence interval implies more variance than a tighter confidence interval
Causation

Criteria for Causation (Sir Bradford Hill)
1. **strength of association**: the frequency with which the factor is found in the disease and the frequency with which it occurs in the absence of disease
2. **consistency**: is it the same outcome with different populations or study design?
3. **specificity**: is the association particular to your intervention and measured outcome?
4. **temporal relationship**: did the exposure occur before the onset of the disease?
5. **biological gradient**: finding a quantitative relationship between the factor and the frequency (e.g. dose response relationship)
6. **biological plausibility**: does the association/causation make biological sense?
7. **coherence**: can the relationship be explained/accounted for based on what we know about the laws of science, logic, etc.?
8. **experimental evidence**: experiment that investigates what happens when the suspected offending agent is removed (e.g. is there improvement?)
9. **analogy**: do other established associations provide a model for this type of the relationship?

**Note**: Not all criteria must be fulfilled to establish scientific causation, and the modern practice of EBM emphasizes 'experimental evidence' as superior to other criteria for experimental causation review. However many causation questions in health cannot be answered with experimental methods.

Assessing Evidence

- critical appraisal is the process of systematically examining research evidence to assess validity, results, and relevance before using it to inform a decision
# Health Services Research

## Continuous Quality Improvement

**Quality Improvement (QI)**
- method of evaluating and improving processes; focusing more on systems and systematic biases, which are thought to be the cause of variation in quality, as opposed to individuals
- taking measures to increase efficiency of action with the purpose of achieving optimal quality

**Quality Assurance**
- management system to assure the quality of health care provided by workers and received by patients
- constantly aims to improve standards and the frequency of attaining those standards
- **five-stage process of quality assurance**
  1. establishment of functional goals
  2. implementation of procedures to achieve those goals
  3. regular assessment of performance relative to the goals
  4. proposal of solutions to close the gap between performance and goals
  5. documentation and reporting of this assessment activity

**Quality Control**
- method of maintaining standards by reviewing the quality of all factors involved in the process

**Continuous Quality Improvement**
- management approach to improve and maintain quality via continuous assessment of potential defects, followed by action to improve process, avoid decrease in quality or correcting process in early stages
- continuous feed-forward process

**Quality Management**
- encompasses quality assurance, quality control, and quality improvement to achieve consistent quality

**Total Quality Management**
- management philosophy for improving quality while controlling costs
- focusing on the system rather than the individual, to ensure decisions are made to support quality and remove barriers to quality inherent in bureaucratic, hierarchical systems

**Audit**
- process of systematic examination of a quality system carried out by internal or external quality auditors
- to determine whether quality processes and results comply with goals, and whether processes have been implemented effectively

**Systems Analyses Tools**
1. 5 Whys: brainstorming to simplify the process of change; continue asking ‘why’ until the root of the problem is discovered
2. Ishikawa Diagrams (i.e. Fishbone Diagrams): identify generic categories of problems that have an overall contribution on the effect

---

**Levels of Evidence: Classifications Cited in Guidelines/Consensus Statements**

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>based on RCTs (or meta-analysis of RCTs) big enough to have low risk of incorporating FP or FN results</td>
</tr>
<tr>
<td>II</td>
<td>based on RCTs too small to provide Level I evidence; may show positive trends that are non-significant, or have a high risk of FN results</td>
</tr>
<tr>
<td>III</td>
<td>based on non-randomized, controlled or cohort studies; case series; case-controlled; or cross-sectional studies</td>
</tr>
<tr>
<td>IV</td>
<td>based on opinion of respected authorities or expert committees, as published consensus conferences/guidelines</td>
</tr>
<tr>
<td>V</td>
<td>opinions of the individuals who have written-reviewed the guidelines (i.e. Level IV evidence), based on experience/knowledge of literature/peer discussion</td>
</tr>
</tbody>
</table>

**Canadian Task Force on Preventive Health Care Grading of Health Promotion Actions**

A: Good evidence to recommend the preventive health measure
B: Fair evidence to recommend the preventive health measure
C: Existing evidence is conflicting and does not allow making a recommendation for or against use of the clinical preventive action, however other factors may influence decision-making
D: Fair evidence to recommend against the preventive health measure
E: Good evidence to recommend against the preventive health measure
I: Insufficient evidence (in quantity and/or quality) to make a recommendation, however other factors may influence decision-making

Source: Canadian Task Force on Representative Health Care. Canadian task force on preventive new grades for recommendations CMAJ 2003;169:207-208
3. **Defect check sheets**: consider all defects and tally up the number of times the defect occurs

4. **Pareto Chart**: x vs. y chart; x-axis = defect categories, y-axis = frequency; plot cumulative frequency on the right y-axis
   - Purpose is to highlight most important among large set of factors contributing to defects/poor quality

### Precede-Proceed Model
- Tool for designing, implementing, and evaluating health interventions/programs

<table>
<thead>
<tr>
<th>PRECEDE Phase</th>
<th>PROCEED Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 1 – Identify the ultimate desired result</td>
<td>Phase 5 – Implementation (design and conduct the intervention)</td>
</tr>
<tr>
<td>Phase 2 – Identify and set priorities among health issues and their behavioural and environmental determinants</td>
<td>Phase 6 – Process Evaluation (determine if the program is implemented as planned)</td>
</tr>
<tr>
<td>Phase 3 – Identify the predisposing, enabling, and reinforcing factors that affect the behaviours and environmental determinants</td>
<td>Phase 7 – Impact Evaluation (measure intermediate objectives – predisposing, enabling, and reinforcing factors)</td>
</tr>
<tr>
<td>Phase 4 – Identify the administrative and policy factors that influence what can be implemented</td>
<td>Phase 8 – Outcome Evaluation (measure desired result)</td>
</tr>
</tbody>
</table>

### Cost Analysis

**Cost Benefit Analysis (CBA)**
- A process of, either explicitly or implicitly, weighing the total expected costs against the total expected benefits of one or more actions in order to choose the best or most profitable option
- All costs are adjusted for the time value of money so that costs that may change over time are expressed on a common basis in terms of their present value

**Cost Effectiveness Analysis (CEA)**
- A comparison of the relative expenditure (costs) and outcomes (effects) of two or more courses of action
- Cost effectiveness analysis is often used where a full cost benefit analysis is inappropriate
- A CEA is commonly expressed in terms of a ratio: the denominator is a gain in health from a measure (e.g., years of life, premature births averted, sight-years gained) and the numerator is the cost of the health gain
- The most commonly used outcome measure is quality-adjusted life years (QALY) (see Quality Adjusted Life Year, PH8)
Outbreak of Infectious Diseases

Definitions

Endemic
- constant presence of disease or infectious agent in a given geographic area or population subgroup (i.e. usual rate of disease)

Outbreak
- occurrence of new cases clearly in excess of the baseline frequency of the disease in a defined community or population over a given period of time
- synonymous with epidemic, although generally considered to be an epidemic that is localized, has an acute onset, or is relatively short in duration

Epidemic
- any disease, infectious or chronic, occurring at a greater frequency than usually expected in a defined community or institutional population over a given time period (i.e. excessive rate of disease)

Pandemic
- epidemic over a wide area, crossing international boundaries, and affecting a large number of people

Attack Rate
- cumulative incidence of infection within a defined group observed during a specific period of time in an epidemic
- calculated by dividing the total number of people who develop clinical disease by the population at risk, usually expressed as a percentage

Secondary Attack Rate
- number of cases among contacts occurring within the incubation period following exposure to the primary case, in relation to the total exposed contacts
- infectiousness reflects the ease of disease transmission and is usually measured by the secondary attack rate

Virulence
- severity of the disease produced by the organism in a given host
- expressed as the ratio of the number of cases of severe and fatal infection to the total number of clinically affected

Case-Fatality Rate (CFR)
- proportion of individuals contracting a disease who die as a result of that disease
- most frequently applied to a specific outbreak of acute disease in which all patients have been followed for an adequate period of time to include all attributable deaths
- must be clearly differentiated from the mortality rate

Mortality Rate/CRude Death Rate
- estimation of the portion of the population that dies during a specified period from all causes of death

Steps to Control an Outbreak

1. Define the Problem
   - is it an outbreak?

2. Appraise Existing Data and Institute a Surveillance System
   - case definition: formulated from the most common symptoms or signs; definition includes the likely date of onset of illness of the first case (e.g. any person with onset of fever higher than 38.5°C and cough within past 28 d)
- active surveillance: identify those who may have been exposed to the infectious agent and who fit the case definition through active efforts, including
  - contacting emergency rooms, physicians’ offices, local schools
  - obtaining records from health units, such as mortality or laboratory records

Infection Control Precautions
(see Infectious Diseases, ID6)
- Contact (impetigo, chicken pox, warts)
  - Wash hands
  - Gloves
  - Gown
  - Wipe equipment after use
- Airborne (TB)
  - Contact precautions PLUS
  - N95 mask (fit tested)
  - Negative pressure room
- Droplet (influenza, mumps, pneumonia)
  - Contact precautions PLUS
  - Goggles/face shield
  - Surgical mask

Active Surveillance
Outreach such as visits or phone calls by the public health/surveillance authority to detect unreported cases (e.g. an infection control nurse goes to the ward and reviews temperature charts to see if any patient has a nosocomial infection)

Passive Surveillance
A surveillance system where the public health/surveillance authority depends on others to submit standardized forms or other means of reporting cases (e.g. ward staff notify infection control when new cases of nosocomial infections are discovered)
3. Formulate Hypotheses and Implement Initial Control Measures
- track outbreak evolution to develop hypotheses about potential source and populations at risk
- case management depends on symptoms, suspected agent, population at risk, and location
- population management requires public health services in the community and infection control teams in hospitals to initiate initial control measures:
  - disseminate information about risk reduction
  - ensure adherence to personal preventative measures (e.g. hand hygiene, personal protective equipment)
  - prevent new cases (e.g. vaccination, post-exposure prophylaxis)
  - decrease risk of propagation (e.g. quarantine)
  - treat existing cases (e.g. antibiotics, antivirals, supportive care)

4. Test the Hypothesis through Analysis of Surveillance Data or Special Studies
- analyze outbreak surveillance data
- generate epidemic curves
  - usually a frequency histogram, with the number of cases plotted on the vertical axis and dates or times of onset along the horizontal axis
  - curve can indicate whether the epidemic (outbreak) has a common source or whether it is propagated
  - **point source epidemic**: exposure is brief and essentially simultaneous
  - **extended source epidemic**: exposure lasts for a period of days to weeks and may be continuous (no irregular peaks) or intermittent (irregularly spaced peaks)
  - **propagated epidemic**: begins with only a few exposed persons but is maintained by person-to-person transmission (e.g. measles/influenza); epidemic curve shows a series of peaks
- use epidemic curves, cross-sectional studies, and/or case-control studies to evaluate hypotheses about cause of outbreak

5. Draw Conclusions and Re-Adjust Hypothesis and Control Measures
- establish cause of outbreak with further epidemiologic investigation and revise initial control measures accordingly

6. Plan for Long-Term Prevention and Control
- implement prevention measures to avoid similar future incidents
  - strengthen resistance of hosts (e.g. immunization)
  - interrupt modes of transmission in environment (e.g. improvements in food processing)
  - communicate outbreak prevention and control strategies to the public

**Infection Control Targets**
- interventions should target host, agent, environment, and their interactions
Environmental Health

**Definition**
- study of conditions in the natural and human-made environment that influence human health and well-being
- environmental exposures
  - four common hazards: chemical, biological, physical, and radiation
  - four main reservoirs: air, food, water, and soil
  - three main routes: inhalation, ingestion, or absorption (skin)
  - usually divided into two main settings
    - workplace (including schools): may see high level exposure in healthy individuals (see *Occupational Health*, PH23)
    - non-workplace: generally low level but chronic exposure; population at risk includes extremes of age, developing fetuses, and ill or immunocompromised individuals
- health impacts of the environment also include factors such as urban planning and how individuals interact with the built environment (e.g. safe pedestrian and bicycle paths are neighbourhood features that can facilitate more active lifestyles among residents)

**Environmental Health Jurisdiction**

</table>

**Risk Assessment**

**Hazard Identification**
- what is the hazard involved?
- assess potential hazards by taking an environmental health history

**Risk Characterization**
- is the identified agent likely to elicit the patient’s current symptoms?
- review known health impacts of the hazard and identify specific properties that contribute to or diminish adverse effects (e.g. evaluate threshold levels)

**Exposure Assessment**
- is the patient’s exposure to the environmental agent sufficient to have caused the current symptoms?
- quantify exposure through direct measurement or by reviewing frequency and nature of contact with hazard

**Air**

**Biological Hazards**
- moulds thrive in moist areas; 10-15% of the population allergic
- bacteria survive as spores and aerosols, can be distributed through ventilation systems (e.g. *Legionella*)
- dust mites (year-round) and pollens (seasonal) can trigger upper and lower-airway symptoms
Chemical Hazards
- ground-level ozone
  - main component of smog with levels increasing in major cities
  - worsens asthma, irritates upper airway
- carbon monoxide (fossil fuel-related, common byproduct of combustion)
  - aggravates cardiac disease at low levels
  - headache, nausea, dizziness at moderate levels
  - fatal at high levels
- sulphur dioxide (fossil fuel-related), nitrogen oxides
  - contribute to acid rain and exacerbate breathing difficulties
- organic compounds at high levels (e.g. benzene, methylene chloride, tetrachloroethylene)
  - tend to be fat-soluble, easily absorbed through skin and difficult to excrete
- heavy metals emissions (e.g. nickel, cadmium, chromium)
  - variety of health effects: upper airway disease, asthma, decreased lung function
- second-hand tobacco smoke
  - respiratory problems, increase risk of lung cancer
  - particulates associated with decreased lung function, asthma, upper airway irritation

Radiation Hazards
- sound waves
  - ionizing radiation
  - radon is naturally produced by soil containing uranium or radium, can contaminate indoor air and is associated with a small proportion of lung cancers
- ultraviolet radiation is increasing due to ozone layer destruction and increases risk of skin cancer
  - non-ionizing radiation
  - visible light, infrared, microwave

Water

Biological Hazards
- mostly due to human and animal waste
- Aboriginal Canadians, rural Canadians at higher risk
- bacteria: Escherichia coli (e.g. Walkerton, ON), Salmonella, Pseudomonas, Shigella
- protozoa: Giardia, Cryptosporidium (e.g. North Battleford, SK)

Chemical/Industrial Hazards
- chlorination by-products (e.g. chloroform can cause cancer at high levels)
- volatile organic compounds, heavy metals, pesticides, and other industrial waste products can be present in groundwater
- fluoride at high levels (greater than that of municipal fluoridation) can cause skeletal fluorosis

Soil

Biological Hazards
- biological contamination: tetanus, Pseudomonas

Chemical Hazards
- contamination sources: rupture of underground storage tanks, use of pesticides and herbicides, percolation of contaminated water runoffs, leaching of wastes from landfills, dust from smelting and coal burning power plants, residue of industrial waste/development (e.g. urban agriculture), lead deposition, leakage of transformers
- most common chemicals: petroleum hydrocarbons, solvents, lead, pesticides, motor oil, other industrial waste products
- health effects
  - infants and toddlers at highest risk of exposure due to hand-mouth behaviours
  - dependent on contaminant: leukemia, kidney damage, liver toxicity, neuromuscular blockade, developmental damage to the brain and nervous system, skin rash, eye irritation, headache, nausea, fatigue

The Walkerton Tragedy
In May 2000, the drinking water system in the town of Walkerton, ON, became contaminated with Escherichia coli O157:H7 and Campylobacter jejuni. Over 2,300 individuals became ill; 27 people developed hemolytic uremic syndrome and 7 individuals died in the outbreak.

Food

Biological Hazards

<tr>
<td>Prion (BSE*)</td>
<td>Creutzfeldt-Jakob disease</td>
</tr>
</tbody>
</table>

*BSE = bovine spongiform encephalopathy

- other biological food contaminants include
  - viruses, mould toxins (e.g. aflatoxin has been associated with liver cancer), parasites (e.g. Toxoplasmosis, tapeworm), paralytic and shellfish poisoning (rare), genetically modified organisms (controversial as to health risks/benefits)

Chemical Hazards

- many persistent organic pollutants are fat-soluble and undergo bioamplification
- drugs (antibiotics, hormones)
- inadequately prepared herbal medications
- food additives and preservatives
  - nitrates highest in cured meats; can be converted to carcinogenic nitrosamines
  - sulphites commonly used as preservatives; associated with sulphite allergy (hives, nausea, shock)
  - pesticide residues
  - older pesticides (e.g. DDT) have considerable human health effects
  - polychlorinated biphenyls (PCBs)
    - effects (severe acne, numbness, muscle spasm, bronchitis) much more likely to be seen in occupationally exposed individuals than in the general population
- dioxins and furans
  - levels highest in fish and marine mammals, also present in breast milk
  - can cause immunosuppression, liver disease, respiratory disease

Occupational Health

- occupational health is the maintenance and promotion of health in the work environment
- services encompass health promotion and protection (primary prevention), disease prevention (secondary prevention), and treatment and rehabilitation (tertiary prevention)
- general bias towards reporting occupational injuries versus occupational disease, as occupational disease is harder to identify

Taking an Occupational Health History

- current and previous job duties
- exposures
  - identification: screen for chemical, metal, dust, biological, and physical hazards as well as psychological stressors; review relevant workplace MSDS
  - assessment: duration, concentration, route, exposure controls (e.g. ventilation, personal protective equipment)
- temporal relationship: changes in symptoms in relationship to work environment
- presence of similar symptoms in co-workers
- non-work exposures: home, neighbourhood, hobbies

Figure 18. Hierarchy of controls for reduction of occupational exposures

### Workplace Legislation

- universal across Canada for corporate responsibility in the workplace: due diligence, application of Workplace Hazardous Materials Information System (WHMIS), existence of joint health and safety committees in the workplace with representatives from workers and management
- jurisdiction in Canada is provincial (90% of Canadian workers), except for 16 federally regulated industries (e.g. airports, banks, highway transport) under the Canada Labour Code
- Ontario’s Occupational Health and Safety Act
  - sets out rights of workers and duties of employers, procedures for dealing with workplace hazards, and law enforcement
  - workers have the right to
    - participate (e.g. have representatives on joint health and safety committees)
    - know (e.g. be trained and have information about workplace hazards)
    - refuse work (e.g. workers can declare tasks they feel are overly dangerous)
    - note: For some occupations, this right is restricted if, for example, danger/risk is normal part of work or refusal would endanger others (e.g. police, firefighters, some health care workers)
  - stop work (e.g. ‘certified’ workers can halt work they feel is dangerous to other workers)
  - employers must take precautions to protect the health and safety of employees and investigate concerns
  - enforced by Ministry of Labour via inspectors
- Health Protection and Promotion Act (HPPA) (Ontario)
  - Medical Officer of Health has right to investigate and manage health hazards where workplace exposures may impact non-workers (e.g. community members living close to the work site)
- Employment and Social Insurance Act (Each province will have their own similar legislation)
  - Establishes Workplace Safety and Insurance Board (WSIB), an autonomous government agency that oversees workplace safety training and administers insurance for workers and employers
  - WSIB decides benefits for workers, which may include reimbursement for
    - Loss of earned income
    - Non-economic loss (e.g. physical, functional, or psychological loss extending beyond the workplace)
    - Loss of retirement income
    - Health care expenses (e.g. first-aid, medical treatment)
    - Survivor benefits (e.g. dependents and spouses can receive benefits)
  - Employers pay for costs (e.g. no government funding)
  - No-fault insurance (e.g. worker has no right to sue the employer) in return for guaranteed compensation for accepted claims
  - Negligence is not considered a factor
  - Physicians are required to provide the WSIB with information about a worker’s health without a medical waiver once a claim is made

### Workplace Health Promotion and Protection

- take action in the workplace so the worker is protected from injury or illness
  - identifying workplace hazards (e.g. through material safety data sheets [MSDS])
  - assessing risk
  - reducing exposure: changes to work environment including elimination, substitution, and isolation of hazard (e.g. engineering controls) more effective than changes to how people work (e.g. administrative controls) and personal protective equipment

### Workplace Disease Prevention and Identification

- monitor workers’ health to prevent the development of disease
  - periodic examinations to facilitate pre-symptomatic diagnosis
  - PFT for asthma (e.g. occupational dust exposure)
  - audiograms for hearing loss (e.g. occupational noise exposure)
  - substance misuse screening where performance impairment is suspected
- work up and diagnose presenting occupational health problems with appropriate laboratory and radiologic investigations
- Occupational Health Statistics
  - 1 in 68 employed workers in 2010 received workers compensation due to injury or harm on the job
  - 4,405 fatal work injuries in the United States in 2013, rate = 3.2/100,000 workers
  - Source: Employment and Social Development Canada. Work-related injuries, 2015
Workplace Treatment and Rehabilitation

- treat injury or illness with safe return to the workplace
- may require rehabilitation, retraining, change in job duties, and/or workers’ compensation (WSIB)
- advise relevant authorities if necessary (e.g. report notifiable diseases to public health, conditions impeding driving to Ministry of Transportation, see Appendix, PH25)

Appendix – Mandatory Reporting

Reportable Diseases

As an essential part of the health system, physicians in Canada are required by law to report certain diseases to public health for the following reasons

1. to control the outbreak
   - if the disease presents an outbreak threat (e.g. measles, Salmonella, respiratory diseases in institutions)
2. to prevent spread
   - if the disease presents a significant threat to individuals or a subset of the population (e.g. Lassa Fever)
3. for surveillance
   - if the disease is preventable with immunization (e.g. polio, diphtheria, congenital rubella)
4. if infected individuals require education, treatment and/or partner notification (e.g. gonorrhea, TB)
5. reporting details (website, office etc.)
   - some are more urgent than others (must contact MOH)
   - physicians should also report unlisted diseases that appear in clusters

The following list is based on the reportable diseases in Ontario for 2014. Each province will have similar legislation

Source: Health Protection and Promotion Act, O. Reg. 559/91, amended to O. Reg.49/07

Acquired Immunodeficiency Syndrome (AIDS)
Acute flaccid paralysis <15 yr
Amoebiasis
Anthrax
Botulism
Brucellosis
Campylobacter enteritis
Chancroid
Chickenpox (Varicella)
Chlamydia trachomatis infections
Cholera
Clostridium difficile associated disease (CDAD) outbreaks in public hospitals
Cryptosporidiosis
Cyclosporiasis
Cytomegalovirus infection, congenital
diabetes, invasive
Diphtheria
Encephalitis, including:
  i. Primary, viral
  ii. Post-infectious
  iii. Vaccine-related
  iv. Subacute sclerosing panencephalitis
  v. Unspecified
Food poisoning, all causes
Gastroenteritis, institutional outbreaks
Giardiasis, except asymptomatic cases
Gonorrhea
Haemophilus influenzae b disease, invasive
Hantavirus pulmonary syndrome
Hepatitis A
Hepatitis B
Hepatitis C
Hepatitis D (Delta hepatitis)
Herpes, neonatal
Human Immunodeficiency Virus (HIV)
Influenza
Lassa Fever
Legionellosis
Measles
Meningitis, acute:
  i. Bacterial
  ii. Viral
  iii. Other
Meningococcal disease, invasive
Mumps
Paralytic shellfish poisoning
Paratyphoid fever
Pertussis (whooping cough)
Plague
Pneumococcal disease, invasive
Poliomyelitis, acute
Psittacosis/Ornithosis
Q Fever
Rabies
Respiratory infection outbreaks in institutions
Rubella
Rubella, congenital syndrome
Salmonellosis
Severe Acute Respiratory Syndrome (SARS)
Shigellosis
Smallpox
Streptococcal infections, Group A invasive
Streptococcal infections, Group B neonatal
Syphilis
Tetanus
Transmissible spongiform encephalopathy, including:
  i. Creutzfeldt-Jakob disease, all types
  ii. Gerstmann-Sträussler-Scheinker syndrome
  iii. Fatal familial insomnia
  iv. Kuru
Trichinosis
Typhoid Fever
Verotoxin-producing E. coli infection
Yellow Fever
Yersinia pestis
Other Reportable Conditions

In addition to reporting diseases, physicians have a legal responsibility to report certain conditions. The list below highlights some reportable conditions for Ontario, but is not exhaustive. See your jurisdiction’s regulatory body for the full list.

Child Abuse – to local Children’s Aid Society (CAS)
- all child abuse and neglect where reasonable grounds to suspect exist (including physical harm, emotional harm, sexual harm, and neglect)
- duty to report is ongoing: if additional reasonable grounds are suspect, a further report to CAS is necessary

Unfit to Drive – to provincial Ministry of Transportation
- all patients with a medical condition (e.g., dementia, untreated epilepsy) that may impede their driving ability
- if a physician does not report and the driver gets into an accident, the physician may be held liable

Unfit to Fly – to federal Ministry of Transportation
- all patients believed to be flight crew members or air traffic controller with a medical or optometric condition that is likely to constitute a hazard to aviation safety

Gunshots Wounds – to local police service
- all patients with a gunshot or stab wounds
- self-inflicted knife wounds are not reportable

## Psychiatric Assessment

### History

**Identifying Data**
- necessary: name, sex, age, ethnicity, marital status, occupation/source of financial support, place and type of residency
- adjunct: makeup of household, religion, education, referral source, known or unknown to treatment team

**Reliability of Patient as a Historian**
- Indicate if, and for what content, collateral source used (e.g. parent, teacher) if patient unable/unwilling to cooperate

**Chief Complaint**
- in patient’s own words, duration

**History of Present Illness**
- reason for seeking help (that day), current symptoms (onset, duration and course), stressors, supports, functional status, relevant associated symptoms (pertinent positives and negatives)
- safety screen: is the patient endangering self or others? dependants at home (e.g. children, pets), ability to drive safely, ability to care for self (e.g. eating, hygiene, taking medications)

### Psychiatric Functional Inquiry

- mood: depression, mania
- anxiety: worries, obsessions, compulsions, panic attacks, phobias, history of trauma
- psychosis: hallucinations, delusions
- suicide/homicide: ideation, plan, intent, history of attempts (see Suicide, PS4)
- organic: EtOH/drug use or withdrawal, illness, dementia

### Past Psychiatric History
- all previous psychiatric diagnoses, psychiatric contacts, treatments (pharmacological and non-pharmacological), and hospitalizations
- include past suicide attempts, substance use/abuse, and legal problems

### Past Medical/Surgical History
- all medical, surgical, neurological (e.g. head trauma, seizures), and psychosomatic illnesses
- current medications, allergies

### Family Psychiatric/Medical History
- family members: ages, occupations, personalities, medical or genetic illnesses and treatments, relationships with parents/siblings
- family psychiatric history: any past or current psychiatric illnesses and hospitalizations, suicide, substance abuse

### Past Personal/Developmental History (as relevant)
- prenatal and perinatal history (desired vs. unwanted pregnancy, maternal and fetal health, domestic violence, maternal substance use, complications of pregnancy/delivery)
- early childhood to age 3 (developmental milestones, activity/attention level, family stability, attachment figures)
- middle childhood to age 11 (school performance, peer relationships, fire-setting, stealing, incontinence)
- late childhood to adolescence (drug/alcohol, legal problems, peer and family relationships)
- physical or sexual abuse in childhood/adolescence
- adulthood (education, occupations, relationships)
- personality before current illness, recent changes in personality
- psychosocial history (puberty, first sexual encounter, romantic relationships, gender roles, sexual dysfunction)

### Screening Questions for Major Psychiatric Disorders

- Have you been feeling down, depressed or hopeless?
- Do you feel anxious or worry about things?
- Has there been a time in your life where you have felt euphoric, extremely talkative, had a lot of energy, and a decreased need for sleep?
- Do you see or hear things that you think other people cannot?
- Have you ever thought of harming yourself or committing suicide?
Mental Status Exam

General Appearance
• dress, grooming, posture, gait, physical characteristics, body habitus, apparent vs. chronological age, facial expression (e.g. sad, suspicious), tattoos, piercings (if numerous or atypical), acute distress or relaxed

Behaviour
• psychomotor activity (agitation, retardation), abnormal movements or lack thereof (tremors, akathisia, tardive dyskinesia, paralysis), attention level and eye contact, attitude toward examiner (ability to interact, level of cooperation)

Speech
• rate (e.g. pressured, slowed), rhythm/fluency, volume, tone, articulation, quantity, spontaneity

Mood and Affect
• mood: subjective emotional state (in patient's own words)
• affect: objective emotional state inferred from emotional responses to stimuli; described in terms of
  ▪ quality (euthymic, depressed, elevated, anxious, irritable)
  ▪ range (full, restricted, flat, blunted)
  ▪ stability (fixed, labile)
  ▪ mood congruence (inferred by reader by comparing mood and affect descriptions)
  ▪ appropriateness to thought content
• some clinicians use 0-10 scales when rating mood to help get a subjective norm for each patient that can help establish changes over time and with treatment

Thought Process/Form
• coherence (coherent, incoherent)
• logic (logical, illogical)
• stream
  ▪ goal-directed: clearly answers questions in a linear, organized, logical fashion
  ▪ circumstantial: speech that is indirect and delayed in reaching its goal; eventually comes back to the point
  ▪ tangential: speech is oblique or irrelevant; does not come back to the original point
  ▪ loosening of associations/ derailment: illogical shifting between topics
  ▪ flight of ideas: quickly skipping from one idea to another where the ideas are marginally connected, usually associated withmania
  ▪ word salad: jumble of words lacking meaning or logical coherence
  ▪ perseveration: repetition of the same verbal or motor response to stimuli
  ▪ echolalia: repetition of phrases or words spoken by someone else
  ▪ thought blocking: sudden cessation of flow of thought and speech
  ▪ clang associations: speech based on sound such as rhyming or punning
  ▪ neologism: use of novel words or of existing words in a novel fashion

Thought Content
• suicidal ideation/homicidal ideation
  ▪ frequency and pervasiveness of thoughts, formulation of plan, means to plan, intent, active vs. passive, protective factors
• preoccupations, ruminations: reflections/thoughts at length, not fixed or false
• obsession: recurrent and persistent thought, impulse, or image which is intrusive or inappropriate and unwanted
  ▪ cannot be stopped by logic or reason
  ▪ causes marked anxiety and distress
  ▪ common themes: contamination, orderliness, sexual, pathological doubt/worry/guilt
  ▪ magical thinking: belief that thinking something will make it happen; normal in children and certain cultures
• ideas of reference: similar to delusion of reference, but less fixed (the reality of the belief is questioned)
• overvalued ideas: unusual/odd beliefs that are not of delusional proportions
• first rank symptoms of schizophrenia: thought insertion/withdrawal/broadcasting
• delusion: a fixed false belief that is out of keeping with a person’s cultural or religious background and is firmly held despite incontrovertible proof to the contrary

Perception
• hallucination: sensory perception in the absence of external stimuli that is similar in quality to a true perception
  ▪ auditory (most common), visual, gustatory, olfactory, tactile
  ▪ illusion: misperception of a real external stimulus (such as mistaking a coat on a rack as a person late at night)
• depersonalization: change in self-awareness such that the person feels unreal, distant, or detached from his or her body, and/or unable to feel emotion
• derealization: feeling that the world/outer environment is unreal
Cognition
- level of consciousness (alert, reduced, obtunded)
- orientation: time, place, person
- memory: immediate, recent, remote
- global evaluation of intellect (below average, average, above average, in keeping with person's education)
- intellectual functions: attention, concentration, calculation, abstraction (proverb interpretation, similarities test), language, communication
- MMSE/MOCA useful as standardized assessment of cognition

Insight
- patient's ability to realize that he or she has a physical or mental illness and to understand its implications (no, limited, partial, full)

Judgment
- patient's ability to understand relationships between facts and draw conclusions that determine one's actions

Assessment and Plan

Historical Multiaxial Model
- since DSM-5, this Model is no longer used for psychiatric diagnosis. Instead, relevant psychiatric and medical diagnoses are simply listed. Nevertheless, we offer it here as a possible framework for psychiatric patient assessment, as many physicians still employ it.

Multiaxial Assessment
- Axis I: differential diagnosis of DSM-5 clinical disorders
- Axis II: personality disorders, developmental disability
- Axis III: general medical conditions potentially relevant to understanding/management of the mental disorder
- Axis IV: psychosocial and environmental issues
- Axis V: Global Assessment of Functioning (GAF, 0 to 100) incorporating effects of axes I to IV

After History and MSE, the assessment and plan is recorded

Assessment/Problem Formulation
- identify predominant symptom cluster (mood, anxiety, psychosis, organic) - causing the most distress/interference, persist when other symptom categories not present (e.g. psychosis in the absence of mood symptoms)
- dominating symptoms will direct differential
c- consider current issues as they relate to an individual's factors in three domains: biological, psychological, and social
d- for each category: predisposing, precipitating, perpetuating, and protecting factors are considered

Approach to Management
- consider short-term and long-term, and three types: biological (e.g. pharmacotherapy), psychological (e.g. CBT), and social (e.g. support group)

Suicide

Importance
- absolutely must be screened for in every encounter; part of risk assessment along with violent/homicidal ideation

Approach
- ask every patient – e.g. “Have you had any thoughts of wanting to kill yourself?”
- classify ideation
  - passive ideation: would rather not be alive but has no active plan for suicide
    - e.g. “I’d rather not wake up” or “I would not mind if a car hit me”
  - active ideation
    - e.g. “I think about killing myself”
- assess risk
  - plan: “Do you have a plan as to how you would end your life?”
  - intent: “Do you think you would actually carry out this plan?” “If not, why not?”
  - past attempts: highest risk if previous attempt in past year
  - ask about lethality, outcome, medical intervention
- assess suicidal ideation
  - onset and frequency of thoughts: “When did this start?” or “How often do you have these thoughts?”
• control over suicidal ideation: "How do you cope when you have these thoughts?" “Could you call someone for help?”
• intended lethality: “Do you want to end your life?” or “What do you think would happen if you actually took those pills?”
• access to means: “How will you get a gun?” or “Which bridge do you think you would go to?”
• time and place: “Have you picked a date and place? Is it in an isolated location?”
• provocative factors: “What makes you feel worse (e.g. being alone)?”
• protective factors: “What keeps you alive (e.g. friends, family, pets, faith, therapist)?”
• final arrangements: “Have you written a suicide note? Made a will? Given away your belongings?”
• practiced suicide or aborted attempts: “Have you ever put the gun to your head?” “Held the medications in your hand?” “Stood at the bridge?”
• ambivalence: “I wonder if there is a part of you that wants to live, given that you came here for help?”

Assessment of Suicide Attempt
• setting (isolated vs. others present/chance of discovery)
• planned vs. impulsive attempt, triggers/stressors
• substance use/intoxication
• medical attention (brought in by another person vs. brought in by self to ED)
• time lag from suicide attempt to ED arrival
• expectation of lethality, dying
• reaction to survival (guilt/remorse vs. disappointment/self-blame)

Epidemiology
• attempted:completed = 20:1
• M:F = 1:4 for attempts, 3:1 for completed

Risk Factors
• epidemiologic factors
  • age: increases after age 14, second most common cause of death for ages 15-24, highest rates in persons >65 yr
  • sex: male
  • race/ethnic background: white or Native Canadians on reserves
  • marital status: widowed/divorced
  • living situation: alone; no children <18 yr old in the household
  • other: stressful life events, access to firearms
• psychiatric disorders
  • mood disorders (15% lifetime risk in depression; higher in bipolar)
  • anxiety disorders (especially panic disorder)
  • schizophrenia (10-15% risk)
  • substance abuse (especially alcohol – 15% lifetime risk)
  • eating disorders (5% lifetime risk)
  • adjustment disorder
  • conduct disorder
  • personality disorders (borderline, antisocial)
• past history
  • prior suicide attempt
  • family history of suicide attempt/completion

Clinical Presentation
• symptoms associated with suicide
  • hopelessness
  • anhedonia
  • insomnia
  • severe anxiety
  • impaired concentration
  • psychomotor agitation
  • panic attacks

Management
• proper documentation of the clinical encounter and rationale for management is essential
  • higher risk (hospitalization needs to be strongly considered):
    • patients with a plan and intention to act on the plan, access to lethal means, recent social stressors, and symptoms suggestive of a psychiatric disorder
    • do not leave patient alone; remove potentially dangerous objects from room
    • if patient refuses to be hospitalized, complete form for involuntary admission (Form 1)
  • lower risk
    • patients who are not actively suicidal, with no plan or access to lethal means

Suicide Risk Factors
SAD PERSONS
Sex (male)
Age >60 yr old
Depression
Previous attempts
Ethanol abuse
Rational thinking loss (delusions, hallucinations, hopelessness)
Suicide in family
Organized plan
No spouse (no support systems)
Serious illness, intractable pain

Suicidal Ideation Assessment
• Asking patients about suicide will not give them the idea or the incentive to commit suicide
• The best predictor of completed suicide is a history of attempted suicide
• The most common psychiatric disorders associated with completed suicide are mood disorders and alcohol abuse
• discuss protective factors and supports in their life, remind them of what they live for, 
  promote survival skills that helped them through previous suicide attempts 
• make a safety plan that could include an agreement that they will: 
  • not harm themselves 
  • avoid alcohol, drugs, and situations that may trigger suicidal thoughts 
  • follow-up with you at a designated time 
  • contact a health care worker, call a crisis line, or go to an emergency department if they 
    feel unsafe or if their suicidal feelings return or intensify 
• depression: consider hospitalization if symptoms severe or if psychotic features are present; 
  otherwise outpatient treatment with good supports and SSRIs/SNRIs 
• alcohol-related: usually resolves with abstinence for a few days; if not, suspect depression 
• personality disorders: crisis intervention, may or may not hospitalize 
• schizophrenia/psychosis: hospitalization might be necessary 
• parasuicide/self-mutilation: long-term psychotherapy with brief crisis intervention when necessary 

**Psychotic Disorders**

**Definition**
- characterized by a significant impairment in reality testing
- delusions or hallucinations (with/without insight into their pathological nature) behaving in a 
  disorganized way so that it is reasonable to infer that reality testing is disturbed

**Differential Diagnosis of Psychosis**

**Approach**
- to differentiate among psychotic disorders and distinguish them from other primary diagnoses 
  with psychotic features, 
- consider symptoms, persistence, and time 
- symptoms: what symptoms exist? The primary diagnosis needs full criteria to be met 
  • mood: depressive episodes with psychotic features, manic episodes with psychotic features 
  • psychotic: consider symptoms in Criterion A of schizophrenia, such as delusions, 
    hallucinations, disorganized speech, grossly disorganized/catatonic behaviour, negative 
    symptoms (i.e. diminished emotional expression or avolition) 
- persistence: is there a time when certain symptom clusters are present without other clusters? 
  • e.g. if there is a period of time with mood symptoms but not psychotic symptoms, consider 
    mood disorder 
  • e.g. if two weeks where psychotic symptoms persist in the absence of mood symptoms, 
    consider schizoaffective disorder 
- time: how long have the symptoms been present?

**Differential**
- primary psychotic disorders: schizophrenia, schizophreniform, brief psychotic, schizoaffective, 
  delusional disorder 
- mood disorders: depression with psychotic features, bipolar disorder (manic or depressive episode 
  with psychotic features) 
- personality disorders: schizotypal, schizoid, borderline, paranoid, obsessive-compulsive 
- general medical conditions: tumour, head trauma, dementia, delirium, metabolic, infection, stroke, 
  temporal lobe epilepsy 
- substance-induced psychosis: intoxication or withdrawal, prescribed medications, toxins

**Table 1. Differentiating Psychotic Disorders**

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Psychotic Symptoms</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brief Psychotic Disorder</td>
<td>≥1 positive symptoms of criterion A</td>
<td>&lt;1 mo</td>
</tr>
<tr>
<td>Schizophreniform Disorder</td>
<td>Criterion A</td>
<td>1-6 mo</td>
</tr>
<tr>
<td>Schizophrenia</td>
<td>Criterion A</td>
<td>&gt; 6 mo</td>
</tr>
<tr>
<td>Schizoaffective Disorder</td>
<td>Criterion A + major mood episode, but ≥2 wk psychotic without mood symptoms</td>
<td>&gt; 1 mo</td>
</tr>
<tr>
<td>Delusional Disorder</td>
<td>Non-bizarre delusions, hallucinations</td>
<td>&gt; 1 mo</td>
</tr>
<tr>
<td>2º to Substance Intoxication/Withdrawal</td>
<td>Delusions or hallucinations During intoxication/withdrawal, not &gt; 1 mo without use</td>
<td></td>
</tr>
<tr>
<td>2º to Mood Disorder</td>
<td>Mood symptoms dominant + delusions/hallucinations (mood congruent)</td>
<td>Psychosis may be present for the duration of the mood episode</td>
</tr>
</tbody>
</table>

**Management of Acute Psychosis and Mania**
- Ensure safety of self, patient, and other patients 
- Have an exit strategy 
- Decrease stimulation 
- Assume a non-threatening stance 
- IM medications (benzodiazepine + antipsychotic) often needed as patient may refuse oral medication 
- Physical restraints may be necessary 
- Do not use antidepressants or stimulants
**Schizophrenia**

**DSM-5 Diagnostic Criteria for Schizophrenia**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least one of these must be (1), (2), or (3)
1. delusions
2. hallucinations
3. disorganized speech (e.g. frequent derailment or incoherence)
4. grossly disorganized or catatonic behaviour
5. negative symptoms (i.e. diminished emotional expression or avolition)

B. decreased level of function: for a significant portion of time since onset, one or more major areas affected (e.g. work, interpersonal relations, self-care) is markedly decreased (or if childhood/adult onset, failure to achieve expected level)

C. at least 6 mo of continuous signs of the disturbance. Must include at least 1 mo of symptoms (or less if successfully treated) that meet Criterion A (i.e. active-phase symptoms) and may include periods of prodromal or residual symptoms (during which, disturbance may manifest by only negative symptoms or by two or more Criterion A symptoms present in an attenuated form (e.g. odd beliefs, unusual perceptual experiences)

D. rule out schizoaffective disorder and depressive or bipolar disorder with psychotic features because either 1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms, or 2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness

E. rule out other causes: GMC, substances (e.g. drug of abuse, medication)

F. if history of autism spectrum disorder or communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations are also present for at least 1 mo (or less if successfully treated)

• **specifiers:** type of episode (e.g. first episode, multiple episodes, continuous), with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis (in acute episode, in partial remission, in full remission)

**Epidemiology**
- prevalence: 0.3-0.7%, M:F = 1:1
- mean age of onset: females late-20s; males early- to mid-20s
- suicide risk: 10% die by suicide, 30% attempt suicide

**Etiology**
- multifactorial: disorder is a result of interaction between both biological and environmental factors
  - genetic: 40% concordance in monozygotic (MZ) twins; 46% if both parents have schizophrenia; 10% of dizygotic (DZ) twins, siblings, children affected; vulnerable genes include Disrupted-in-Schizophrenia 1 (DISC1); neuregulin 1 (NRG 1); dystrobrevin binding protein / dysbindin (DTNBP1); catechol-O-methyltransferase (COMT); danino acid oxidase activator (DAOA); metabotropic glutamate receptor 3 (GRM3); and brain-derived neurotrophic factor (BDNF)
  - neurochemistry (“dopamine hypothesis”): excess activity in the mesolimbic dopamine pathway may mediate the positive symptoms of psychosis, while decreased dopamine in the prefrontal cortex may mediate negative and cognitive symptoms. GABA, glutamate, and ACh dysfunction are also thought to be involved
  - neuroanatomy: decreased frontal lobe function; asymmetric temporal/limbic function; decreased basal ganglia function; subtle changes in thalamus, cortex, corpus callosum, and ventricles; cytoarchitectural abnormalities
  - neuroendocrinology: abnormal growth hormone, prolactin, cortisol, and ACTH
  - neuropsychology: global defects seen in attention, language, and memory suggest lack of connectivity of neural networks
  - environmental: indirect evidence of cannabis use, geographical variance, winter season of birth, obstetrical complications, and prenatal viral exposure

**Pathophysiology**
- neurodegenerative theory
- natural history may be a rapid or gradual decline in function and ability to communicate
- glutamate system may mediate progressive degeneration by excitotoxic mechanism which leads to production of free radicals
- neurodevelopmental theory: abnormal development of the brain from prenatal life
- neurons fail to migrate correctly, make inappropriate connections, and break down in later life
- inappropriate apoptosis during neurodevelopment resulting in faulty connections between neurons

**Comorbidity**
- substance-related disorders
- anxiety disorders
- decreased life expectancy because of associated medical conditions (e.g. weight gain, diabetes, metabolic syndrome, CV/pulmonary disease)

**Disorganized Behaviours in Schizophrenia**
- Catatonic stupor: fully conscious, but immobile, mute, and unresponsive
- Catatonic excitement: uncontrolled and aimless motor activity, maintaining bizarre positions for a long time
- Stereotypy: repeated but non-goal-directed movement (e.g. rocking)
- Maniamerisms: goal-directed activities that are odd or out of context (e.g. grimacing)
- Echopraxia: imitates movements and gestures of another
- Automatic obedience: carries out simple commands in robot-like fashion
- Negativism: refuses to cooperate with simple requests for no apparent reason
- Inappropriate affect, neglect of self-care, other odd behaviours (random shouting)

**Relationship Between Duration of Untreated Psychosis (DUP) and Outcome in First-Episode Schizophrenia**
- **Purpose:** To review the association between DUP and symptom severity at first treatment contact, and between DUP and treatment outcomes.
- **Study Characteristics:** Critical review and meta-analysis of 43 studies with 4,177 patients.
- **Participants:** Patients with non-affective psychotic disorders at or close to first treatment.
- **Results:** Shorter DUP was associated with greater response to antipsychotic treatment, as measured by global psychopathology, positive symptoms, negative symptoms, and functional outcomes. At the time of treatment initiation, longer DUP was associated with the severity of negative symptoms but not with the severity of positive symptoms, global psychopathology, or neurocognitive function.
- **Conclusions:** DUP may be a potentially modifiable prognostic factor.
Management of Schizophrenia
- biological / somatic
  - acute treatment and maintenance: antipsychotics (haloperidol, risperidone, olanzapine, paliperidone, clozapine if refractory); often regimens of IM q2-4 weeks used in severe cases to ensure compliance
  - adjunctive: ± mood stabilizers (for aggression/impulsiveness - lithium, valproate, carbamazepine) ± anxiolytics ± ECT
  - treat for at least 1-2 years after the first episode, at least 5 years after multiple episodes (relapse causes severe deterioration)
- psychosocial
- psychotherapy: individual, family (important), group: supportive, CBT (see Table 14, PS43)
  - ACT (Assertive Community Treatment): mobile mental health teams that provide individualized treatment in the community and help patients with medication adherence, basic living skills, social support, job placements, resources
- social skills training, employment programs, disability benefits
- housing (group home, boarding home, transitional home)

Course and Prognosis
- majority of individuals display some type of prodromal phase
- course is variable: some individuals have exacerbations and remissions and others remain chronically ill; accurate prediction of the long-term outcome is not possible
- negative symptoms may be prominent early in the illness and may become more prominent and more disabling later on; positive symptoms appear and typically diminish with treatment
- over time: 1/3 improve, 1/3 remain the same, 1/3 worsen

Schizophreniform Disorder
Diagnosis
- criteria A, D, and E of schizophrenia are met; but episode lasts for at least 1 mo but less than 6 mo
- if the symptoms have extended past 6 mo the diagnosis becomes schizophrenia
- specifiers: with/without good prognostic features (e.g. acute onset, confusion, good premorbid functioning, absence of blunt/flat affect), with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis

Treatment
- similar to acute schizophrenia

Prognosis
- better than schizophrenia; begins and ends more abruptly; good pre- and post-morbid function

Brief Psychotic Disorder
Diagnosis
- criteria A1-A4, D, and E of schizophrenia are met; an episode of the disorder lasts for at least 1 d, but less than 1 mo with eventual full return to premorbid level of functioning
- specifiers: with/without marked stressors, with postpartum onset, with catatonia, current severity
- can occur after a stressful event or postpartum (see Postpartum Mood Disorders, PS12)

Treatment
- secure environment, antipsychotics, anxiolytics

Prognosis
- good, self-limiting, should return to pre-morbid function within 1 mo

Schizoaffective Disorder
DSM-5 Diagnostic Criteria for Schizoaffective Disorder (Reformatted)
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. concurrent psychosis (criterion A of schizophrenia) and major mood episode - uninterrupted period of illness
B. delusions or hallucinations for 2 or more wk in the absence of a major mood episode during the lifetime duration of the illness
C. major mood episode symptoms are present for the majority of the total duration of the active and residual periods of the illness
D. the disturbance is not attributable to the effects of a substance or another medical condition
- specifiers: bipolar type, depressive type, with catatonia, type of episode, severity
- one-third as prevalent as schizophrenia; schizoaffective disorder bipolar type more common in young adults, schizoaffective disorder depressive type more common in older adults
- depressive symptoms correlated with higher suicide risk
Treatment
• antipsychotics, mood stabilizers, antidepressants

Prognosis
• between that of schizophrenia and of mood disorder

Delusional Disorder

DSM-5 Diagnostic Criteria for Delusional Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. the presence of one (or more) delusions with a duration of 1 mo or longer
B. criterion A for schizophrenia has never been met
    Note: hallucinations, if present, are not prominent and are related to the delusional theme
C. apart from the impact of the delusion(s) or its ramifications, functioning is not markedly impaired, and behaviour is not obviously bizarre or odd
D. if manic or major depressive episodes have occurred, these have been brief relative to the duration of the delusional periods
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition and is not better explained by another mental disorder
• subtypes: erotomanic, grandiose, jealous, persecutory, somatic, mixed, unspecified
• further specify: bizarre content, type of episode (e.g. first episode, multiple episode), severity

Treatment
• psychotherapy, antipsychotics, antidepressants

Prognosis
• chronic, unremitting course but high level of functioning; a portion will progress to schizophrenia

Mood Disorders

Definitions
• mood disorders are characterized by the presence of diagnosable mood episodes
• mood episodes represent a combination of symptoms comprising a predominant mood state that is abnormal in quality or duration (e.g. major depressive, manic, mixed, hypomanic). DSM-5 Criteria for mood episodes are listed below.
• types of mood disorders include
• depressive (major depressive disorder, persistent depressive disorder)
• bipolar (bipolar I/II disorder, cyclothymia)
• secondary to general medical condition, substances, medications, other psychiatric issue
• accurate diagnosis of a mood disorder requires a careful past medical and psychiatric history to detect past mood episodes and to rule out whether these episodes were secondary to substance use, a medical condition, a loss, etc.

Medical Workup of Mood Disorder
• routine screening: physical exam, CBC, thyroid function test, extended electrolytes, urinalysis, drug screen, medications list
• additional screening: neurological consultation, chest X-ray, ECG, CT head

Mood Episodes

DSM-5 Diagnostic Criteria for Major Depressive Episode
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. ≥5 of the following symptoms have been present during the same 2 wk period and represent a change from previous functioning; at least one of the symptoms is either 1) depressed mood or 2) loss of interest or pleasure (anhedonia)
    Note: Do not include symptoms that are clearly attributable to another medical condition
• depressed mood most of the day, nearly every day, as indicated by either subjective report or observation made by others
• markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day
• significant and unintentional weight loss, weight gain, or decrease/increase in appetite nearly every day
• insomnia or hypersomnia nearly every day
• psychomotor agitation or retardation nearly every day
• fatigue or loss of energy nearly every day
• feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)
- diminished ability to think or concentrate, or indecisiveness, nearly every day
- recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide
B. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
C. the episode is not attributable to the direct physiological effects of a substance or a GMC

**DSM-5 Criteria for Manic Episode**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting $\geq 1$ wk and present most of the day, nearly every day (or any duration if hospitalization is necessary)
B. during the period of mood disturbance and increased energy or activity, $\geq 3$ of the following symptoms have persisted (4 if the mood is only irritable) and have been present to a significant degree and represent a noticeable change from usual behaviour
  - inflated self-esteem or grandiosity
  - decreased need for sleep (e.g. feels rested after only 3 h of sleep)
  - more talkative than usual or pressure to keep talking
  - flight of ideas or subjective experience that thoughts are racing
  - distractibility (i.e. attention too easily drawn to unimportant or irrelevant external stimuli)
  - increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation
  - excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g. engaging in unrestrained shopping sprees, sexual indiscretions, or foolish business investments)
C. the mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features
D. the episode is not attributable to the physiological effects of a substance or another medical condition

**Hypomanic Episode**
- criterion A and B of a manic episode is met, but duration is $\geq 4$ d
- episode associated with an uncharacteristic change in functioning that is observable by others but not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization
- absence of psychotic features. (If these are present the episode is, by definition, manic)

**Mixed Features**
- an episode specifier in bipolar or depression that indicates the presence of both depressive and manic symptoms concurrently, classified by the disorder and primary mood episode component (e.g. bipolar disorder, current episode manic, with mixed features)
- clinical importance due to increased suicide risk
- if found in patient diagnosed with major depression, high index of suspicion for bipolar disorder
- while meeting the full criteria for a major depressive episode, the patient has on most days $\geq 3$ of criteria B for a manic episode
- while meeting the full criteria for a manic/hypomanic episode, the patient has on most days $\geq 3$ of criteria A for a depressive episode. (The following criterion A cannot count: psychomotor agitation, insomnia, difficulties concentrating, weight changes)

**Depressive Disorders**

**MAJOR DEPRESSIVE DISORDER**

**DSM-5 Diagnostic Criteria for Major Depressive Disorder (MDD)**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of a MDE
B. the MDE is not better accounted for by schizoaffective disorder and is not superimposed on schizophrenia, schizophreniform disorder, delusional disorder, or psychotic disorder NOS
C. there has never been a manic episode or a hypomanic episode

**Note:** This exclusion does not apply if all of the manic-like, or hypomanic-like episodes are substance or treatment-induced or are due to the direct physiological effects of another medical condition

**specifiers:** with anxious distress, mixed features, melancholic features, atypical features, mood-congruent psychotic features, mood-incongruent psychotic features, catatonia, peripartum onset, seasonal pattern
single vs. recurrent is an episode descriptor that carries prognostic significance. Recurrent is classified as the patient having two or more distinct MDE episodes; to be considered separate the patient must have gone 2 consecutive months without meeting criteria.

**Epidemiology**
- lifetime prevalence: 12%
- peak prevalence age 15-25 yr (M:F = 1:2)

**Etiology**
- biological
  - genetic: 65-75% MZ twins; 14-19% DZ twins, 2-4 fold increased risk in first-degree relatives
  - neurotransmitter dysfunction: decreased activity of 5-HT, NE, and DA at the level of the synapse; changes in GABA and glutamate; various changes in brain circuitry and functional connectivity detectable by fMRI
  - neuroendocrine dysfunction: excessive HPA axis activity
  - neuroanatomy: decreased hippocampal volume, increased ventricle sizes
  - neurophysiologic: decreased REM latency and slow-wave sleep; increased REM length
  - immunologic: increased pro-inflammatory cytokines IL-6 and TNF
  - secondary to medical condition, medication, substance use disorder
- psychosocial
  - psychodynamic (e.g. low self-esteem, unconscious aggression towards self or loved ones, disordered attachment)
  - cognitive (e.g. distorted schemata, Beck’s cognitive triad: negative views of the self, the world, and the future)
  - environmental factors (e.g. job loss, bereavement, history of abuse or neglect, early life adversity)
  - comorbid psychiatric diagnoses (e.g. anxiety, substance abuse, developmental disability, dementia, eating disorder)

**Risk Factors**
- sex: F>M, 2:1
- family history: depression, alcohol abuse, suicide attempt or completion
- childhood experiences: loss of parent before age 11, negative home environment (abuse, neglect)
- personality: neuroticism, insecure, dependent, obsessive
- recent stressors: illness, financial, legal, relational, academic
- lack of intimate, confiding relationships or social isolation
- low socioeconomic status

**Depression in the Elderly**
- affects about 15% of community residents >65 yr old; up to 50% in nursing homes
- high suicide risk due to social isolation, chronic medical illness, decreased independence
- suicide peak: males aged 80-90; females aged 50-65
- dysthymia may not be a reliable indicator of depression in those >85 yr
- often present with somatic complaints (e.g. changes in weight, sleep, energy) or anxiety symptoms
- may have prominent cognitive changes after onset of mood symptoms (dementia syndrome of depression)
- see Table 3, PS22, for a comparison of delirium and dementia

**Treatment**
- lifestyle: increased aerobic exercise, mindfulness-based stress reduction, zinc supplementation
- biological: SSRIs, SNRIs, other antidepressants, somatic therapies (see Pharmacotherapy, PS44, and Somatic Therapies, PS52)
- 1st line pharmacotherapy: sertraline, escitalopram, venlafaxine, mirtazapine
- for partial or non-response can change class or add augmenting agent: bupropion, quetiapine-XR, aripiprazole, lithium
- typical response to antidepressant treatment: physical symptoms improve at 2 wk, mood/cognition by 4 wk, if no improvement after 4 wk at a therapeutic dosage alter regimen
- ECT: currently fastest and most effective treatment for MDD. Consider in severe, psychotic or treatment-resistant cases
- rTMS: early data support efficacy equivalent to ECT with good safety and tolerability
- phototherapy: especially if seasonal component, shift work, sleep dysregulation
- psychological
  - individual therapy (psychodynamic, interpersonal, CBT), family therapy, group therapy
  - social: vocational rehabilitation, social skills training
  - experimental: magnetic seizure therapy, deep brain stimulation, vagal nerve stimulation, ketamine

**Prognosis**
- one year after diagnosis of MDD without treatment: 40% of individuals still have symptoms that are sufficiently severe to meet criteria for MDD, 20% continue to have some symptoms that no longer meet criteria for MDD, 40% have no mood disorder
PERSISTENT DEPRESSIVE DISORDER

DSM-5 Diagnostic Criteria for Persistent Depressive Disorder

Note: in DSM-IV-TR this was referred to as Dysthymia

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for ≥2 yr
B. presence, while depressed, of ≥2 of the following
   • poor appetite or overeating
   • insomnia or hypersomnia
   • low energy or fatigue
   • low self-esteem
   • poor concentration or difficulty making decisions
   • feelings of hopelessness
C. during the 2 yr period (1 yr for children or adolescents) of the disturbance, the person has never been without the symptoms in criteria A and B for more than 2 mo at a time
D. criteria for a major depressive disorder may be continuously present for 2 yr
E. there has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder
F. the disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder.
G. the symptoms are not due to the direct physiological effects of a substance or another medical condition
H. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

Epidemiology

• lifetime prevalence: 2-3%; M=F

Treatment

• psychological
  • traditionally psychotherapy was the principal treatment for dysthymia; recent evidence suggests some benefit but generally inferior to pharmacological treatment. Combinations of the two may be most efficacious
  • biological
    • antidepressant therapy: SSRIs (e.g. sertraline, paroxetine) TCAs (e.g. imipramine) as an outpatient

Postpartum Mood Disorders

Postpartum “Blues”

• transient period of mild depression, mood instability, anxiety, decreased concentration; considered to be normal changes in response to fluctuating hormonal levels, the stress of childbirth, and the increased responsibilities of motherhood
• occurs in 50-80% of mothers; begins 2-4 d postpartum, usually lasts 48 h, can last up to 10 d
• does not require psychotropic medication
• usually mild or absent: feelings of inadequacy, anhedonia, thoughts of harming baby, suicidal thoughts

MAJOR DEPRESSIVE DISORDER WITH PERIPARTUM ONSET
(PARTUM DEPRESSION)

Diagnosis

• MDD that occurs during pregnancy or in the 4 wk following delivery

Clinical Presentation

• typically lasts 2-6 mo; residual symptoms can last up to 1 yr
• may present with psychosis; rare (0.2%), usually associated with mania, but also with MDE
• severe symptoms include extreme disinterest in baby, suicidal and infanticidal ideation

Epidemiology

• occurs in 10% of mothers, risk of recurrence 50%

Risk Factors

• previous history of a mood disorder (postpartum or otherwise), family history of mood disorder
• psychosocial factors: stressful life events, unemployment, marital conflict, lack of social support, unwanted pregnancy, colicky or sick infant

Selective Serotonin Reuptake Inhibitors in Pregnancy and Infant Outcomes

Pediatr Child Health 2011;16:562-563

Study: Canadian Paediatric Society (CPS) Clinical practice guidelines.

Recommendations: It is important to treat depression in pregnancy. There is no evidence that SSRIs increase the risk of major malformations. There is conflicting evidence concerning the association of paroxetine and cardiac malformations. SSRIs are not contraindicated while breast-feeding.
Treatment
• psychotherapy (CBT or IPT)
• short-term safety of maternal SSRIs for breastfeeding infants established; long-term effects unknown
• if depression severe or psychotic symptoms present, consider ECT

Prognosis
• impact on child development: increased risk of cognitive delay, insecure attachment, behavioural disorders
• treatment of mother improves outcome for child at 8 mo through increased mother-child interaction

Bipolar Disorders

BIPOLAR I / BIPOLAR II DISORDER

Definition
• Bipolar I Disorder
  • disorder in which at least one manic episode has occurred
  • if manic symptoms lead to hospitalization, or if there are psychotic symptoms, the diagnosis is BP I
  • commonly accompanied by at least 1 MDE but not required for diagnosis
  • time spent in mood episodes: 53% asymptomatic, 32% depressed, 9% cycling/mixed, 6% hypo/manic
• Bipolar II Disorder
  • disorder in which there is at least 1 MDE, 1 hypomanic and no manic episodes
  • while hypomania is less severe than mania, Bipolar II is not a “milder” form of Bipolar I
  • time spent in mood episodes: 46% asymptomatic, 50% depressed, 1% cycling/mixed, 2% hypo/manic
  • a great masquerader, Bipolar II is often missed due to the severity and chronicity of depressive episodes and low rates of spontaneous reporting and recognition of hypomanic episodes

Classification
• classification of bipolar disorder involves describing the disorder (I or II) and the current or most recent mood episode as either manic, hypomorphic, or depressed
• specifiers: with anxious distress, depressed with mixed features, hypo/manic with mixed features, melancholic features, atypical features, mood-congruent or -incongruent psychotic features, catatonia, peripartum onset, seasonal pattern, rapid cycling (4+ mood episodes in a 1 yr)

Epidemiology
• lifetime prevalence: 1% BPI, 1.1% BPII, 2.4% Subthreshold BPD; M:F = 1:1
• age of onset: teens to 20s, usually MDE first, manic episode 6-10 years after, average age of first manic episode 32 yr

Risk Factors
• genetic: 60-65% of bipolar patients have family history of major mood disorders, especially bipolar disorders
• clinical features predictive of bipolar > unipolar diagnosis given history of MDE: early age of onset (<25 yr), increased number of MDEs, psychotic symptoms, postpartum onset, anxiety disorders (especially separation, panic), antidepressant failure due to early “poop out” or hypomanic symptoms, early impulsivity and aggression, substance abuse, cyclothymic temperament

Treatment
• lifestyle: psychoeducation for patient and supports on cycling nature of illness, ensure regular check ins, develop early warning system, “emergency plan” for manic episodes, promote stable routine (sleep, meals, exercise)
• biological: lithium, anticonvulsants, antipsychotics, ECT (if refractory); monotherapy with antidepressants should be avoided
  • mood stabilizers vary in their ability to “treat” (reduce symptoms acutely) or “stabilize” (prevent relapse and recurrence) manic and depressive symptoms; multi-agent therapy is common
  • treating mania: lithium, valproate, carbamazepine (2nd line), SGA, ECT, benzodiazepines (for acute agitation)
  • preventing mania: same as above but usually at lower dosages, minus benzodiazepines
  • treating depression: lithium, lurasidone, quetiapine, lamotrigine, antidepressants (only with mood stabilizer), ECT
  • preventing depression: same as above plus aripiprazole, valproate (note: quetiapine first line in treating bipolar II depression)
  • mixed episode or rapid cycling: multi-agent therapy, lithium or valproate + SGA (lurasidone, aripiprazole, olanzapine)
• psychological: supportive or psychodynamic psychotherapy, CBT, IPT or interpersonal social rhythm therapy, family therapy
• social: vocational rehabilitation, consider leave of absence from school/work, assess capacity to manage finances, drug and EtOH cessation, sleep hygiene, social skills training, education and recruitment of family members

Course and Prognosis
• high suicide rate (15% mortality from suicide), especially in mixed states
• BP I and II are chronic conditions with a relapsing and remitting course featuring alternating manic and depressive episodes; depressive symptoms tend to occur more frequently and last longer than manic episodes
• can achieve high level of functioning between episodes
• may switch rapidly between depression and mania without any period of euthymia in between
• high recurrence rate for mania – 90% will have a subsequent episode in the next 5 yr
• long term follow up of BP I – 15% well, 45% well with relapses, 30% partial remission, 10% chronically ill

CYCLOTHYMIA

Diagnosis
• presence of numerous periods of hypomanic and depressive symptoms (not meeting criteria for full hypomanic episode or MDE) for ≥2 yr; never without symptoms for >2 mo
• never have met criteria for MDE, manic or hypomanic episodes
• symptoms are not due to the direct physiological effects of a substance or GMC
• symptoms cause clinically signifcant distress or impairment in social, occupational, or other important areas of functioning

Treatment
• similar to Bipolar I: mood stabilizer ± psychotherapy, avoid antidepressant monotherapy, treat any comorbid substance use disorder

Anxiety Disorders

Definition
• anxiety is a universal human characteristic involving tension, apprehension, or even terror
• serves as an adaptive mechanism to warn about an external threat by activating the sympathetic nervous system (fight or flight)
• manifestations of anxiety can be described through
  • physiology: main brain structure involved is the amygdala (fear conditioning);
    neurotransmitters involved include 5-HT, cholecystokinin, epinephrine, norepinephrine, DA
  • psychology: one’s perception of a given situation is distorted which causes one to believe it is threatening in some way
  • behaviour: once feeling threatened, one responds by escaping or facing the situation, thereby causing a disruption in daily functioning
• anxiety becomes pathological when:
  • fear is greatly out of proportion to risk/severity of threat
  • response continues beyond existence of threat or becomes generalized to other similar or dissimilar situations
  • social or occupational functioning is impaired
  • often comorbid with substance use and depression

Differential Diagnosis

Table 2. Differential Diagnosis of Anxiety Disorders

<table>
<thead>
<tr>
<th>Category</th>
<th>Conditions</th>

</tbody>
</table>

Medical Workup of Anxiety Disorder
• routine screening: physical exam, CBC, thyroid function test, electrolytes, urinalysis, urine drug screening
• additional screening: neurological consultation, chest X-ray, ECG, CT head
### Panic Disorder

**DSM-5 Diagnostic Criteria for Panic Disorder**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. recurrent unexpected panic attacks - a panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time four (or more) of the following symptoms occur
- palpitations, pounding heart, or accelerated heart rate
- sweating
- trembling or shaking
- sensations of shortness of breath or smothering
- feelings of choking
- chest pain or discomfort
- nausea or abdominal distress
- feeling dizzy, unsteady, light-headed, or faint
- chills or heat sensations
- paresthesias (numbness or tingling sensations)
- derealization (feeling of unreality) or depersonalization (being detached from oneself)
- fear of losing control or "going crazy"
- fear of dying

B. 1 mo (or more) of “anxiety about panic attacks” - at least one of the attacks has been followed by one or both of the following:
- persistent concern or worry about additional panic attacks or their consequences
- a significant maladaptive change in behaviour related to the attacks

C. the disturbance is not attributable to the physiological effects of a substance or another medical condition

D. the disturbance is not better explained by another mental disorder

**Epidemiology**
- prevalence: 2-5% (one of the top five most common reasons to see a family doctor); M:F = 1:2-3
- onset: average early-mid 20s, familial pattern

**Treatment**
- psychological
  - CBT: interoceptive exposure (eliciting symptoms of a panic attack and learning to tolerate the symptoms without coping strategies); cognitive restructuring (addressing underlying beliefs regarding the panic attacks), relaxation techniques (visualization, box-breathing)
- pharmacological
  - SSRIs: fluoxetine, citalopram, paroxetine, fluvoxamine, sertraline
  - SNRI: venlafaxine
  - with SSRIs/SNRIs start with low doses, titrate up slowly
  - anxiety disorders often require treatment at higher doses for a longer period of time than depression (i.e. full response may take up to 12 wk)
  - to prevent non-compliance due to physical side effects, explain symptoms to expect prior to initiation of therapy
  - other antidepressants (mirtazapine, MAOIs)
    - consider avoiding bupropion or TCAs due to stimulating effects (exacerbate anxious symptoms)
  - benzodiazepines (short-term, low dose, regular schedule, long half-life, avoid prn usage)

**Prognosis**
- 6-10 yr post-treatment: 30% well, 40-50% improved, 20-30% no change or worse
- clinical course: chronic, but episodic with psychosocial stressors

### Agoraphobia

**DSM-5 Diagnostic Criteria for Agoraphobia**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

• “Anxiety about not being able to escape, > 6 mo”

A. marked fear or anxiety about two (or more) of the following five situations:
- using public transportation
- being in open spaces
- being in enclosed places
- standing in line or being in a crowd
- being outside of the home alone

B. the individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of developing panic-like symptoms or other incapacitating or embarrassing symptoms
C. the agoraphobic situations almost always provoke fear or anxiety
D. the agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety
E. the fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context
F. the fear, anxiety, or avoidance is persistent, typically lasting ≥6 mo
G. the fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning
H. if another medical condition is present, the fear, anxiety, or avoidance is clearly excessive
I. the fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder and are not related exclusively to obsessions, perceived defects or flaws in physical appearance, reminders of traumatic events, or fear of separation

Note: agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned

Treatment
• as per panic disorder

Generalized Anxiety Disorder

DSM-5 Diagnostic Criteria for Generalized Anxiety Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance)
B. the individual finds it difficult to control the worry
C. the anxiety and worry are associated with three (or more) of the following six symptoms (with at least some symptoms having been present for more days than not for the past 6 mo)
1. restlessness or feeling keyed up or on edge
2. being easily fatigued
3. difficulty concentrating or mind going blank
4. irritability
5. muscle tension
6. sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep)
D. the anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition
F. the disturbance is not better explained by another mental disorder

Epidemiology
• 1 yr prevalence: 3-8%; M:F = 1:2
• if considering only those receiving inpatient treatment, ratio is 1:1
• most commonly presents in early adulthood

Treatment
• lifestyle: caffeine and EtOH avoidance, sleep hygiene
• psychological: CBT including relaxation techniques, mindfulness
• biological
  ▪ SSRIs and SNRIs are 1st line (paroxetine, escitalopram, sertraline, venlafaxine XL)
  ▪ 2nd line: buspirone (tid dosing), bupropion (caution due to stimulating effects),
  ▪ add-on benzodiazepines (short-term, low dose, regular schedule, long half-life, avoid prn usage)
  ▪ β-blockers not recommended

Prognosis
• chronically anxious adults become less so with age
• depends on pre-morbid personality functioning, stability of relationships, work, and severity of environmental stress
• difficult to treat

Phobic Disorders

Specific Phobia
• definition: marked and persistent (> 6 mo) fear that is excessive or unreasonable, cued by presence or anticipation of a specific object or situation
• lifetime prevalence 12-16%; M:F ratio variable
• types: animal/insect, environment (heights, storms), blood/injection/injury, situational (airplane, closed spaces), other (loud noise, clowns)
Social Phobia (Social Anxiety Disorder)
- **Definition**: marked and persistent (> 6 mo) fear of social or performance situations in which one is exposed to unfamiliar people or to possible scrutiny by others; fearing he/she will act in a way that may be humiliating or embarrassing (e.g. public speaking, initiating or maintaining conversation, dating, eating in public)
- **12 month prevalence rate may be as high as 7%; M:F ratio approximately equal**

Diagnostic Criteria for Phobic Disorders
- exposure to stimulus almost invariably provokes an immediate anxiety response; may present as a panic attack
- person recognizes fear as excessive or unreasonable
- situations are avoided or endured with anxiety/distress
- significant interference with daily routine, occupational/social functioning, and/or marked distress

Treatment
- **psychological**
  - cognitive behaviour therapy (focusing on both in vivo and virtual exposure therapy, gradually facing feared situations)
  - behavioural therapy is more efficacious than medication
- **biological**
  - SSRIs/SNRIs (e.g. fluoxetine, paroxetine, sertraline, venlafaxine), MAOIs
  - β-blockers or benzodiazepines in acute situations (e.g. public speaking)

Prognosis
- chronic

### Obsessive-Compulsive Disorder

**DSM-5 Diagnostic Criteria for Obsessive-Compulsive Disorder**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. **presence of obsessions, compulsions, or both**
   - obsessions are defined by (1) and (2)
     1. recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and cause marked anxiety or distress in most individuals
     2. the individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e. by performing a compulsion; see below)
   - compulsions are defined by (1) and (2)
     1. repetitive behaviours (e.g. hand washing, ordering, checking) or mental acts (e.g. praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
     2. behaviours mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviours or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive

B. the obsessions or compulsions are time-consuming (e.g. take >1 h/d) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

C. the obsessive-compulsive symptoms are not attributable to the physiological effects

D. the disturbance is not better explained by the symptoms of another mental disorder

**Epidemiology**
- 12 mo prevalence 1.1-1.8%; females affected at slightly higher rates than males
- rate of OCD in first-degree relatives is higher than in the general population

**Treatment**
- CBT: exposure with response prevention (ERP) – involves exposure to feared situations with the addition of preventing the compulsive behaviours; cognitive strategies include challenging underlying beliefs
- pharmacotherapy: SSRIs/SNRIs (12-16 week trials, higher doses vs. depression), clomipramine; adjunctive antipsychotics (risperidone)

**Prognosis**
- tends to be refractory and chronic
Trauma- and Stressor-Related Disorders

Post-Traumatic Stress Disorder

DSM-5 Diagnostic Criteria for Post-Traumatic Stress Disorder

A. exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways
   1. directly experiencing the traumatic event(s)
   2. witnessing, in person, the event(s) as it occurred to others
   3. learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental
   4. experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g. first responders collecting human remains: police officers repeatedly exposed to details of child abuse)

B. presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred
   1. recurrent, involuntary, and intrusive distressing memories of the traumatic event(s)
   2. recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s)
   3. dissociative reactions (e.g. flashbacks) in which the individual feels or acts as if the traumatic event(s) were occurring
   4. intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)
   5. marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)

C. persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by one or both of the following
   1. avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)
   2. avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)

D. negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. inability to remember an important aspect of the traumatic event(s)
   2. persistent and exaggerated negative beliefs or expectations about oneself, others, or the world
   3. persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others
   4. persistent negative emotional state (e.g. fear, horror, anger, guilt, or shame)
   5. markedly diminished interest or participation in significant activities
   6. feelings of detachment or estrangement from others
   7. persistent inability to experience positive emotions

E. marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. irritable behaviour and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects
   2. reckless or self-destructive behaviour
   3. hypervigilance
   4. exaggerated startle response
   5. problems with concentration
   6. sleep disturbance (e.g. difficulty falling or staying asleep or restless sleep)

F. duration of the disturbance (criteria B, C, D, and E) is more than 1 mo

G. the disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning

H. the disturbance is not attributable to the physiological effects of a substance or another medical condition

Epidemiology
- prevalence of 7% in general population
- men's trauma is most commonly combat experience/physical assault; women's trauma is usually physical or sexual assault

Treatment
- psychotherapy, CBT
  - ensure safety and stabilize: e.g. emotional regulation techniques (e.g. breathing, relaxation)
  - once coping mechanisms established, can explore/mourn trauma - challenge dysfunctional beliefs, etc.
  - reconnect and integrate - exposure therapy, etc.

Acute Stress Disorder
- May be a precursor to PTSD
- Similar symptoms to PTSD
- Symptoms persist 3 d after a trauma until 1 mo after the exposure
• biological  
  † SSRIs (e.g. paroxetine, sertraline)  
  † prazosin (for treating disturbing dreams and nightmares)  
  † benzodiazepines (for acute anxiety)  
  † adjunctive atypical antipsychotics (risperidone, olanzapine)  
• eye movement desensitization and reprocessing (EMDR): an experimental method of reprocessing memories of distressing events by recounting them while using a form of dual attention stimulation such as eye movements, bilateral sound, or bilateral tactile stimulation (its use is controversial because of limited evidence)

Complications  
• substance abuse, relationship difficulties, depression, impaired social and occupational functioning disorders, personality disorders

Adjustment Disorder  
• a versatile clinical entity designed to capture patients who have difficulty coping with a stressful life event or situation and develop acute, often transient, emotional or behavioural symptoms that resemble less severe versions of other psychiatric conditions

DSM-5 Diagnostic Criteria for Adjustment Disorder  
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. the development of emotional or behavioural symptoms in response to an identifiable stressor(s) occurring within 3 mo of the onset of the stressor(s)  
B. these symptoms or behaviours are clinically significant as evidenced by either of the following:  
  † marked distress that is in excess of what would be expected from exposure to the stressor  
  † significant impairment in social or occupational (academic) functioning  
C. the stress-related disturbance does not meet criteria for another mental disorder and is not merely an exacerbation of a pre-existing mental disorder  
D. the symptoms do not represent normal bereavement  
E. once the stressor (or its consequences) has terminated, the symptoms do not persist for more than an additional 6 mo  
  † specifiers: with depressed mood, with anxiety, with mixed anxiety/depression, with conduct disturbance, with mixed disturbance of conduct/emotions, unspecified

Classification  
• types of stressors  
  † single (e.g. termination of romantic relationship)  
  † multiple (e.g. marked business difficulties and marital problems)  
  † recurrent (e.g. seasonal business crises)  
  † continuous (e.g. living in a crime-ridden neighbourhood)  
  † developmental events (e.g. going to school, leaving parental home, getting married, becoming a parent, failing to attain occupational goals, retirement)

Epidemiology  
• F:M 2:1, prevalence 2-8% of the population

Treatment  
• brief psychotherapy: individual or group (particularly useful for patients dealing with unique and specific medical issues; e.g. colostomy or renal dialysis groups), crisis intervention  
• biological  
  † benzodiazepines may be used for those with significant anxiety symptoms (short-term, low-dose, regular schedule)

Bereavement

Clinical Presentation  
• bereavement is a normal psychological and emotional reaction to a significant loss, also called grief or mourning  
• length and characteristics of “normal” bereavement are variable between individuals/cultures; however, there are general commonalities in the symptoms, course and expected resolution that allow clinicians to monitor for abnormal severity  
• normal response: protest → searching and acute anguish → despair and detachment → reorganization  
• if a patient meets criteria for MDD, even in the context of a loss or bereavement scenario, they are still diagnosed with MDD  
• presence of the following symptoms may indicate abnormal grief/presence of MDD  
  † guilt about things other than actions taken or not taken by the survivor at the time of death  
  † thoughts of death other than the survivor feeling that they would be better off dead or should have died with the deceased person; morbid preoccupation with worthlessness

Risk Factors for Poor Bereavement Outcome  
• Poor social supports  
• Unanticipated death or lack of preparation for death  
• Highly dependent relationship with deceased  
• High initial distress  
• Other concurrent stresses and losses  
• Death of a child  
• Pre-existing psychiatric disorders, especially depression and separation anxiety
marked psychomotor retardation; prolonged and marked functional impairment
hallucinatory experiences other than thinking that the survivor hears the voice of or
transiently sees the image of the deceased person
dysphoria that is pervasive and independent of thoughts or triggers of the deceased, absence
of mood reactivity
after 12 mo, if patient continues to yearn/long for the deceased, experience intense sorrow/
emotional pain in response to the death, remain preoccupied with the deceased or with their
circumstance of death, then may start to consider a diagnosis of “persistent complex bereavement
disorder”

Treatment
• support and watchful waiting should be first line, as well as education and normalization of the
grief process
• screen for increased alcohol, cigarette and drug use
• normal grief should not be treated with antidepressant or antianxiety medication, as it is important
to allow the person to experience the whole mourning process to achieve resolution
• psychosocial: for those needing additional support, complex grief/bereavement, or significant
MDD, grief therapy (individual or group) is indicated
• pharmacotherapy: MDD present, past history of mood disorders, severe or autonomous symptoms

Neurocognitive Disorders

Delirium
• see Neurology, N21 and Geriatric Medicine, GM3

DSM-5 Diagnostic Criteria for Delirium
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. attention and awareness: disturbance in attention (i.e. reduced ability to direct, focus, sustain,
and shift attention) and awareness (reduced orientation to the environment)
B. acute and fluctuating: disturbance develops over short period of time (usually hours to days),
represents a change from baseline attention and awareness, and tends to fluctuate in severity
during the course of a day
C. cognitive changes: an additional disturbance in cognition (e.g. memory deficit, disorientation,
language, visuospatial ability, or perception)
D. not better explained: disturbances in criteria A and C are not better explained by another
neurocognitive disorder (pre-existing, established, or evolving) and do not occur in the context
of a severely reduced level of arousal (e.g. coma)
E. direct physiological cause: evidence that disturbance is a direct physiological consequence of
another medical condition, substance intoxication or withdrawal (i.e. due to a drug of abuse or
medication), toxin, or is due to multiple etiologies
• Note: can have HYPERactive, HYPOPactive, or MIXED presentation

Clinical Presentation and Assessment
• common symptoms
  ▪ distractibility, disorientation (time, place, rarely person)
  ▪ misinterpretations, illusions, hallucinations
  ▪ speech/language disturbances (dysarthria, dysnomia, dysgraphia)
  ▪ affective symptoms (anxiety, fear, depression, irritability, anger, euphoria, apathy)
  ▪ shifts in psychomotor activity (gropping/picking at clothes, attempts to get out of bed when
unsafe, sudden movements, sluggishness, lethargy)
  ▪ Folstein Mini Mental Status Exam is helpful to assess baseline of altered mental state (i.e. score will
improve as symptoms resolve)

Risk Factors
• hospitalization (incidence 10-56%)
• previous delirium
• nursing home residents (incidence 60%)
• polypharmacy (e.g. anticholinergic)
• old age (especially males)
• severe illness (e.g. cancer, AIDS)
• recent anesthesia or surgery
• substance abuse
• pre-existing cognitive impairment, brain pathology, psychiatric illness

Etiology
• Infectious (encephalitis, meningitis, UTI, pneumonia)
• Withdrawal (alcohol, barbiturates, benzodiazepines)
• Acute metabolic disorder (electrolyte imbalance, hepatic or renal failure)
• Trauma (head injury, post-operative)

Bereavement is associated with a significant increase in morbidity and mortality acutely following the loss, with
effects seen up to 1 yr after
Loneliness is the most common symptom that continues to persist
in normal bereavement and may last several years
Confusion Assessment Method (CAM) for Diagnosis of Delirium
Highly sensitive and specific method to
diagnosis delirium
Part 1: an assessment instrument that
screens for overall cognitive impairment.
Part 2: includes four features found best able to distinguish delirium from other
cognitive impairments
Need (1) + (2) + (3 or 4)
(1) Acute onset and fluctuating course
(2) Inattention
(3) Disorganized thinking
(4) Altered level of consciousness -
hyperactive or hypoactive
Visual hallucinations are organic until
proven otherwise
• CNS pathology (stroke, hemorrhage, tumour, seizure disorder, Parkinson’s)
• Hypoxia (anemia, cardiac failure, pulmonary embolus)
• Deficiencies (vitamin B₁₂, folic acid, thiamine)
• Endocrinopathies (thyroid, glucose, parathyroid, adrenal)
• Acute vascular (shock, vasculitis, hypertensive encephalopathy)
• Toxins: substance use, sedatives, opioids (especially morphine), anesthetics, anticholinergics, anticonvulsants, dopaminergic agents, steroids, insulin, glyburide, antibiotics (especially quinolones), NSAIDs
• Heavy metals (arsenic, lead, mercury)

Investigations
• standard: CBC and differential, electrolytes, Ca²⁺, PO₄³⁻, Mg²⁺, glucose, ESR, LFTs, Cr, BUN, TSH, vitamin B₁₂, folate, albumin, urine C&S, R&M
• as indicated: ECG, CXR, CT head, toxicology/heavy metal screen, VDRL, HIV, LP, blood cultures, EEG (typically abnormal - generalized slowing or fast activity, can also be used to rule out underlying seizures or post-ictal states as etiology)
• indications for CT head: focal neurological deficit, acute change in status, anticoagulant use, acute incontinence, gait abnormality, history of cancer

Management
• intrinsic
  ▪ identify and treat underlying cause immediately
  ▪ stop all non-essential medications
  ▪ maintain nutrition, hydration, electrolyte balance and monitor vitals
• extrinsic
  ▪ environment: quiet, well-lit, near window for cues regarding time of day
  ▪ optimize hearing and vision
  ▪ room near nursing station for closer observation; constant care if patient jumping out of bed, pulling out lines
  ▪ family member present for reassurance and re-orientation
  ▪ frequent orientation - calendar, clock, reminders
• biological
  ▪ low dose, high potency antipsychotics: haloperidol has the most evidence; reasonable alternatives include risperidone, olanzapine (more sedating, less QT prolongation), quetiapine (if EPS), aripiprazole
  ▪ benzodiazepines only to be used in alcohol withdrawal delirium; otherwise, can worsen delirium
  ▪ try to minimize anticholinergic side effects
  ▪ physical restraints if patient becomes violent

Prognosis
• up to 50% 1 yr mortality rate after episode of delirium

Major Neurocognitive Disorder (Dementia)

• see Neurology, N22

DSM-5 Diagnostic Criteria for Major Neurocognitive Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. evidence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on
  1. concern of the individual, a knowledgeable informant, or the clinician that there has been a significant decline in cognitive function;
  2. substantial impairment in cognitive performance, preferably documented by standardized neuropsychological testing or, in its absence, another quantified clinical assessment
B. cognitive deficits interfere with independence in everyday activities (i.e. at a minimum, requiring assistance with complex instrumental activities of daily living such as paying bills or managing medications)
  ▪ Note: if do not interfere in B, and impairments are mild-moderate in A, considered “mild neurocognitive disorder”; see Neurology, N21

C. cognitive deficits do not occur exclusively in the context of a delirium
D. cognitive deficits are not better explained by another mental disorder (e.g. major depressive disorder, schizophrenia)

Dosing for Haloperidol in Delirium
Typical dose 0.5-1 mg
Dosing schedule varies with clinical approach: PRN often used, but QHS or QHS and QAM also employed to account for hypoactive delirium, which is otherwise often missed

The 4 As of Dementia
A - Amnesia
A - Aphasia
A - Apraxia
A - Agnosia

The “Mini Cog” Rapid Assessment
• 3 word recall
• Clock drawn to “10 past 11”
• Animal lists
Specify whether due to

Epidemiology
- prevalence increases with age: 10% in patients >65 yr of age; 25% in patients >85 yr of age
- prevalence is increased in people with Down’s syndrome and head trauma
- Alzheimer’s disease comprises >50% of cases; vascular causes comprise approximately 15% of cases (other causes of dementia neurocognitive disorder – see Neurology, N25-N27)
- average duration of illness from onset of symptoms to death is 8-10 yr

Subtypes
- with or without behavioural disturbance (e.g. wandering, agitation)
- early-onset: age of onset <65 yr
- late-onset: age of onset >65 yr

Investigations (rule out reversible causes)
- standard: see Delirium, PS20
- as indicated: VDRL, HIV, SPECT, CT head in dementia
- indications for CT head: same as for delirium, plus: age <60, rapid onset (unexplained decline in cognition or function over 1-2 mo), dementia of relatively short duration (<2 yr), recent significant head trauma, unexplained neurological symptoms (new onset of severe headache/seizures)

Management
- see Neurology, N22 for further management
- treat underlying medical problems and prevent others
- provide orientation cues for patient (e.g. clock, calendar)
- provide education and support for patient and family (e.g. day programs, respite care, support groups, home care)
- consider long-term care plan (nursing home) and power of attorney/living will
- inform Ministry of Transportation about patient’s inability to drive safely
- consider pharmacological therapy
  - cholinesterase inhibitors (e.g. donepezil [Aricept®], rivastigmine, galantamine) for mild to severe disease
  - NMDA receptor antagonist (e.g. memantine) for moderate to severe disease
  - low-dose neuroleptics (e.g. risperidone, quetiapine), antidepressants or trazodone if behavioural or emotional symptoms prominent – start low and go slow
  - reassess pharmacological therapy every 3 mo

Substance-Related and Addictive Disorders

• a neurobiological disorder involving compulsive drug seeking and drug taking, despite adverse consequences, with loss of control over drug use (think issues with the "3 Cs": compulsive, consequences, control)

Overview
• dependence is the hallmark of substance use disorders and comes in the following forms:
  ▪ behavioural: substance-seeking activities and pathological use patterns
  ▪ physical: physiologic withdrawal effects without use
  ▪ psychological: continuous or intermittent cravings for the substance to avoid dysphoria or attain drug state
• abuse: drug use that deviates from the approved social or medical pattern, usually causing impairment or disruption to function in self or others
• these disorders are usually chronic with a relapsing and remitting course

Epidemiology
• 47% of those with substance abuse have mental health problems
• 29% of those with a mental health disorder have a substance use disorder
• 47% of those with schizophrenia and 25% of those with an anxiety disorder have a substance use disorder

Etiology
• almost all drugs (and activities) of abuse increase dopamine in the nucleus accumbens, an action that contributes to their euphoric properties and, with repeated use, to their ability to change signalling pathways in the brain's reward system
• substance use disorders arise from multifactorial interactions between genes (personality, neurobiology) and environment (low socioeconomic status, substance-using peers, abuse history, chronic stress)

Diagnosis
• substance use disorders are measured on a continuum from mild to severe based on the number of criteria met within 12 mo
  ▪ mild: 2-3
  ▪ moderate: 4-5
  ▪ severe: 6 or more
• each specific substance is meant to be addressed as a separate use disorder (e.g. a single patient may have moderate alcohol use disorder, and a mild stimulant use disorder) and diagnosed utilizing the same overarching criteria
• criteria for substance use disorders (PEC WITH MCAT)
  ▪ use despite Physical or psychological problem (e.g. alcoholic liver disease or cocaine related nasal problems)
  ▪ failures in important External roles at work/school/home
  ▪ Craving or a strong desire to use substance
  ▪ Withdrawal
  ▪ continued use despite Interpersonal problems
  ▪ Tolerance, needing to use more substance to get same effect
  ▪ use in physically Hazardous situations
  ▪ More substance used or for longer period than intended
  ▪ unsuccessful attempts to Cut down
  ▪ Activities given up due to substance
  ▪ excessive Time spent on using or finding substance

</table>
General Approach to Assessment
• must be appropriate to the patient's current state of change (see Population Health and Epidemiology, Health Promotion Strategies, PH7, for Prochaska's Stages of Change Model)
• patients will only change when the pain of change appears less than the pain of staying the same
• provider can help by providing psychoeducation (emphasize neurobiologic model of addiction), motivation, and hope
• principles of motivational interviewing (see Psychotherapy, PS43)
  - non-judgmental stance
  - space for patient to talk and reflect
  - offer accurate empathic reflections back to patient to help frame issues
• although not explicitly in the substance use disorder criteria, the following questions are important to characterize HPI and safety
  - when was the last time you used? how long can you go without using?
  - by what route (oral ingestion, insufflation, smoking, IV) do you usually use?
  - are there any triggers that you know will cause you to use?
  - how has your substance use affected your work, school, relationships?
  - substances can be very expensive, how do you support your drug use?
  - have you experienced medical or legal consequences of your use?
  - any previous attempts to cut down or quit, did you experience any withdrawal symptoms?

General Approach to Treatment
• encourage and offer referral to evidence based services
  - social: 12-step programs (alcoholics anonymous, narcotics anonymous), family education and support
  - psychological therapy: addiction counselling, motivational enhancement therapy (MET), CBT, contingency management, group therapy, family therapy, marital counseling
  - medical management (differs for substances): acute detoxification, pharmacologic agents to aid maintenance
• harm reduction whenever possible: safe-sex practices, avoid driving while intoxicated, avoiding substances with child care, safe needle practices/exchange, pill-testing kits, reducing tobacco use
• comorbid psychiatric conditions: many will resolve with successful treatment of the substance use disorder but patients who meet full criteria for another disorder should be treated for that disorder with psychological and pharmacologic therapies

Nicotine
• see Family Medicine, FM11

Alcohol
• see Family Medicine, FM13 and Emergency Medicine, ER54

History
• CAGE: validated screening questionnaire
  C ever felt the need to Cut down on drinking?
  A ever felt Annoyed at criticism of your drinking?
  G ever feel Guilty about your drinking?
  E ever need a drink first thing in morning (Eye opener)?
  • for men, a score of ≥2 is a positive screen; for women, a score of ≥1 is a positive screen
  • if positive CAGE, then assess further to distinguish between problem drinking and alcohol dependence

Table 4. Canada’s Low-Risk Alcohol Drinking Guidelines

<table>
<thead>
<tr>
<th>Moderate Drinking</th>
</tr>
</thead>
<tbody>
<tr>
<td>Men: 3 or less/d (≤15/wk)</td>
</tr>
<tr>
<td>Women: 2 or less/d (≤10/wk)</td>
</tr>
<tr>
<td>Elderly: 1 or less/d</td>
</tr>
</tbody>
</table>

Alcohol Intoxication
• legal limit for impaired driving is 10.6 mmol/L (50 mg/dL) reached by 2-3 drinks/h for men and 1-2 drinks/h for women
• coma can occur with >60 mmol/L (non-tolerant drinkers) and 90-120 mmol/L (tolerant drinkers)

Alcohol Withdrawal
• occurs within 12-48 h after prolonged heavy drinking and can be life-threatening
• alcohol withdrawal can be described as having 4 stages, however not all stages may be experienced
  - stage 1 (onset 12-18 h after last drink): “the shakes” tremor, sweating, agitation, anorexia, cramps, diarrhea, sleep disturbance
  - stage 2 (onset 7-48 h): alcohol withdrawal seizures, usually tonic-clonic, non-focal and brief
  - stage 3 (onset 48 h): visual, auditory, olfactory or tactile hallucinations

Confabulations: the fabrication of imaginary experiences to compensate for memory loss

Make sure to ask about other alcohols: mouthwash, rubbing alcohol, methanol, ethylene glycol, aftershave (may be used as a cheaper alternative)
stage 4 (onset 3-5 d): delirium tremens, confusion, delusions, hallucinations, agitation, tremors, autonomic hyperactivity (fever, tachycardia, HTN)
- course: almost completely reversible in young; elderly often left with cognitive deficits
- mortality rate 20% if untreated

Management of Alcohol Withdrawal
- monitor using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) scoring system
  - areas of assessment include
    - physical (5): nausea and vomiting, tremor, agitation, paroxysmal sweats, headache/fullness in head
    - psychological/cognitive (2): anxiety, orientation/clouding of sensorium
    - perceptual (3): tactile disturbances, auditory disturbances, visual disturbances
  - all categories are scored from 0-7 (except: orientation/sensorium 0-4), maximum score of 67
  - mild <10, moderate 10-20, severe >20

Table 5. CIWA-A Scale Treatment Protocol for Alcohol Withdrawal

Wernicke-Korsakoff Syndrome
- alcohol-induced amnestic disorders due to thiamine deficiency
- necrotic lesions: mammillary bodies, thalamus, brainstem
- Wernicke's encephalopathy (acute and reversible): triad of nystagmus (CN VI palsy), ataxia, and confusion
- Korsakoff’s syndrome (chronic and only 20% reversible with treatment): anterograde amnesia and confabulations; cannot occur during an acute delirium or dementia and must persist beyond usual duration of intoxication/withdrawal
- management
  - Wernicke’s: thiamine 100 mg PO OD x 1-2 wk
  - Korsakoff’s: thiamine 100 mg PO bid/tid x 3-12 mo

Treatment of Alcohol Use Disorder
- non-pharmacological
  - see General Approach to Treatment, PS24
- pharmacological
  - naltrexone (Revia®): opioid antagonist, shown to be successful in reducing the “high” associated with alcohol, moderately effective in reducing cravings, frequency or intensity of alcohol binges
  - disulfiram (Antabuse®): blocks oxidation of alcohol (blocks acetaldehyde dehydrogenase); with alcohol consumption, acetaldehyde accumulates to cause a toxic reaction (vomiting, tachycardia, death); if patient relapses, must wait 48 h before restarting Antabuse®; prescribed only when treatment goal is abstinence. RCT evidence is generally poor or negative
  - acamprosate (Campral®): NMDA glutamate receptor antagonist; useful in maintaining abstinence and decreasing cravings

Opioids
- types of opioids: heroin, morphine, oxycodone, Tylenol #3* (codeine), hydromorphone, fentanyl
- major risks associated with the use of contaminated needles: increased risk of hepatitis B and C, bacterial endocarditis, HIV/AIDS

Acute Intoxication
- direct effect on receptors in CNS resulting in decreased pain perception, sedation, decreased sex drive, nausea/vomiting, decreased GI motility (constipation and anorexia), and respiratory depression

Delirium Tremens (alcohol withdrawal delirium)
- Autonomic hyperactivity (diaphoresis, tachycardia, increased respiration)
- Hand tremor
- Insomnia
- Psychomotor agitation
- Anxiety
- Nausea or vomiting
- Tonic-clonic seizures
- Visual/tactile/auditory hallucinations
- Persecutory delusions

OxyNEO vs. OxyContin
As of 2012, OxyContin was no longer available in Canada and was replaced by a new formulation of oxycodone called OxyNEO. OxyNEO is reported to be more tamper-resistant than OxyContin as the tablet is more difficult to crush. Furthermore, if OxyNEO is crushed, and added to water, it forms a thick gel-like substance that cannot be easily injected.
Toxic Reaction
- typical syndrome includes shallow respirations, miosis, bradycardia, hypothermia, decreased level of consciousness
- management
  - ABCs
  - IV glucose
  - naloxone hydrochloride (Narcan®): 0.4 mg up to 2 mg IV for diagnosis
  - treatment: intubation and mechanical ventilation, ± naloxone drip, until patient alert without naloxone (up to >48 h with long-acting opioids)
- caution with longer half-life; may need to observe for toxic reaction for at least 24 h

Withdrawal
- symptoms: depression, insomnia, drug-craving, myalgias, nausea, chills, autonomic instability (lacrimation, rhinorrhea, piloerection)
- onset: 6-12 h; duration: 5-10 d
- complications: loss of tolerance (overdose on relapse), miscarriage, premature labour
- management: long-acting oral opioids (methadone, buprenorphine), α-adrenergic agonists (clonidine)

Cocaine
- street names: blow, C, coke, crack, flake, freebase, rock, snow
- alkaloid extracted from leaves of the coca plant; blocks presynaptic uptake of dopamine (causing euphoria), norepinephrine and epinephrine (causing vasospasm, HTN)
- self-administered by inhalation, insufflation, or intravenous route

Intoxication
- elation, euphoria, pressured speech, restlessness, sympathetic stimulation (e.g. tachycardia, mydriasis, sweating)
- prolonged use may result in paranoia and psychosis

Overdose
- medical emergency: HTN, tachycardia, tonic-clonic seizures, dyspnea, and ventricular arrhythmias
- treatment with IV diazepam to control seizures and propanolol or labetalol to manage HTN and arrhythmias

Withdrawal
- initial “crash” (1-48 h): increased sleep, increased appetite
- withdrawal (1-10 wk): dysphoric mood plus fatigue, irritability, vivid unpleasant dreams, insomnia or hyperactivity, psychomotor agitation or retardation
- complications: relapse, suicide (significant increase in suicide during withdrawal period)
- management: supportive management

Treatment of Cocaine Use Disorder
- see General Approach to Treatment, PS24
- no pharmacologic agents have widespread evidence or acceptance of use

Complications
- cardiovascular: arrhythmias, MI, CVA, ruptured AAA
- neurologic: seizures
- psychiatric: psychosis, paranoia, delirium, suicidal ideation
- other: nasal septal deterioration, acute/chronic lung injury “crack lung”, possible increased risk of connective tissue disease
Amphetamines

- includes prescription medications for ADHD such as Ritalin® and Adderall®
- intoxication characterized by euphoria, improved concentration, sympathetic and behavioural hyperactivity and at high doses can mimic psychotic mania, can eventually cause coma
- chronic use can produce a paranoid psychosis which can resemble schizophrenia with agitation, paranoia, delusions and hallucinations
- withdrawal symptoms include dysphoria, fatigue, and restlessness
- treatment of amphetamine induced psychosis: antipsychotics for acute presentation, benzodiazepines for agitation, β-blockers for tachycardia, hypertension

Cannabis

- cannabis (marijuana) is the most commonly used illicit drug
- psychoactive substance: delta-9-tetrahydrocannabinol (Δ9-THC)
- intoxication characterized by tachycardia, conjunctival vascular engorgement, dry mouth, altered sensorium, increased appetite, increased sense of well-being, euphoria/laughter, muscle relaxation, impaired performance on psychomotor tasks including driving
- high doses can cause depersonalization, paranoia, anxiety and may trigger psychosis and schizophrenia if predisposed
- chronic use associated with tolerance and an apathetic, motivational state, increases risk of later manic episodes
- cessation following heavy use does produce a significant withdrawal syndrome: irritability, anxiety, insomnia, decreased food intake
- treatment of cannabis use disorder: see General Approach to Assessment, PS24

Hallucinogens

- types of hallucinogens by primary action
  - 5-HT2A agonists: LSD, mescaline (peyote), psilocybin mushrooms, DMT (ayahuasca)
  - NMDA antagonists: PCP, ketamine
  - μ-opioid agonists: salvia divinorum, ibogaine
  - 5-HT2A agonists are most commonly used, intoxication characterized by tachycardia, HTN, mydriasis, tremor, hyperpyrexia, and a variety of perceptual, mood and cognitive changes (rarely, if ever, deadly; treat vitals symptomatically)
- psychological effects of high doses: depersonalization, derealization, paranoia, and anxiety (panic with agoraphobia)
- tolerance develops rapidly (hours-days) to most hallucinogens so physical dependency is virtually impossible, although psychological dependency and problematic usage patterns can still occur
- chronic use associated with tolerance and an apathetic, motivational state, increases risk of later manic episodes
- support, reassurance, diminished stimulation; benzodiazepines or high potency antipsychotics seldom required (if used, use small doses), minimize use of restraints
- long term adverse effects: controversial role in triggering psychiatric disorders, particularly mood or psychosis, thought to be chiefly in individuals with genetic or other risk factors
- Hallucinogen Persisting Perception Disorder: DSM-5 diagnosis characterized by long lasting, spontaneous, intermittent recurrences of visual perceptual changes reminiscent of those experienced with hallucinogen exposure

<td>Psychological distress, accidents due to intensity of experience and lack of body control, in overdose, decreased LOC, respiratory depression, catatonia</td>
</tr>
</tbody>
</table>

Cannabinoid Hyperemesis Syndrome
An interesting and relatively new clinical phenomenon associated with chronic cannabis use characterized by cyclical, recurrent severe nausea, vomiting, and colicky pain. Possibly due to increased potency of available THC products. Patients often present to ED in acute distress with no evidence of specific GI pathology. Many patients will successfully self-medicate with hot baths or showers

Medical Uses of Marijuana
- Anorexia-cachexia (AIDS, cancer)
- Spasticity, muscle spasms (multiple sclerosis, spinal cord injury)
- Levodopa-induced dyskinesia (Parkinson’s Disease)
- Controlling tics and obsessive-compulsive behaviour (Tourette’s syndrome)
- Reducing intra-ocular pressure (glaucoma)

Cannabis Use and Risk of Psychotic or Affective Mental Health Outcomes: A Systematic Review
The Lancet 2007;370:119-129
Purpose: To review the evidence for cannabis use and occurrence of psychotic or affective mental health outcomes.
Study Characteristics: A meta-analysis of 35 population-based longitudinal studies, or case-control studies nested within longitudinal designs.
Results: There was an increased risk of any psychotic outcome in individuals who had ever used cannabis (pooled adjusted odds ratio = 1.41, 95% CI 1.20-1.65). Findings were consistent with a dose-response effect, with greater risk in people who used cannabis more frequently (2.09, 95% CI 1.54-2.64). Findings for depression, suicidal thoughts, and anxiety outcomes were less consistent. In both cases (psychotic and affective outcomes), a substantial confounding effect was present.
Conclusions: The findings are consistent with the view that cannabis increases risk of psychotic outcomes independent of transient intoxication effects, although evidence is less strong for affective outcomes. Although cannabis use and the development of psychosis are strongly associated, it is difficult to determine causality and it is possible that the association results from confounding factors or bias. The authors did conclude that there is sufficient evidence to warn young people that using cannabis could increase their risk of developing a psychotic illness later in life.

Emerging Medical Uses of Hallucinogens
Many hallucinogens are currently under investigation for therapeutic benefits; LSD & Psilocybin for end of life anxiety, MDMA for PTSD, Ketamine for rapid treatment of depression, ibogaine derivatives for addiction

Date Rape Drugs
- GHB
- Flunitrazepam (Rohypnol®)
- Ketamine
Table 6. The Mechanism and Effects of Common “Club Drugs” (continued)

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Effect</th>
<th>Adverse Effects</th>
</tr>
</thead>
</table>
| Methamphetamine   | Amphetamine stimulant, induces norepinephrine, dopamine, and serotonin release | Rush begins in min, effects last 6-8 h, increased activity, decreased appetite, general sense of well-being, tolerance occurs quickly, users often binge and crash | Short-term use: high agitation, rage, violent behaviour, occasionally hyperthermia and convulsions  
Long-term use: addiction, anxiety, confusion, insomnia, paranoia, auditory and tactile hallucinations (especially formication), delusions, mood disturbance, suicidal and homicidal thoughts, stroke, may be contaminated with lead, and IV users may present with acute lead poisoning |
| Phencyclidine      | Not understood, used by veterinarians to immobilize large animals          | Amnestic, euphoric, hallucinatory state                                                                                           | Horizontal/vertical nystagmus, myoclonus, ataxia, autonomic instability (treat with diazepam IV), prolonged agitated psychosis (treat with haloperidol); high risk for suicide; violence towards others; High dose can cause coma |

Somatic Symptom and Related Disorders

General Characteristics
- physical signs and symptoms lacking objective medical support in the presence of psychological factors that are judged to be important in the initiation, exacerbation, or maintenance of the disturbance
- cause significant distress or impairment in functioning
- symptoms are produced unconsciously and are not the result of malingering or factitious disorder, which are disorders of voluntary “faking” of symptoms (or intentionally inducing, e.g. injecting feces) for secondary gain
- primary gain: somatic symptom represents a symbolic resolution of an unconscious psychological conflict; serves to reduce anxiety and conflict with no external incentive
- secondary gain: the sick role; external benefits obtained or unpleasant duties avoided (e.g. work)

Management of Somatic Symptom and Related Disorders
- brief, regular scheduled visits with GP to facilitate therapeutic relationship and help patient feel cared for
- limit number of physicians involved in care, minimize medical investigations; coordinate necessary investigations
- emphasis on what the patient can change and control; the psychosocial coping skills, not their physical symptoms (functional recovery > explanation of symptoms)
- do not tell patient it is “all in their head,” emphasize these disorders are real entities or functional in nature
- psychotherapy: CBT, mindfulness interventions, biofeedback, conflict resolution
- minimize psychotropic drugs: anxiolytics in short-term only, antidepressants for comorbid depression and anxiety

Somatic Symptom Disorder

DSM-5 Diagnostic Criteria for Somatic Symptom Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. one or more somatic symptoms that are distressing or result in significant disruption of daily life
B. excessive thoughts, feelings, or behaviours related to the somatic symptoms or associated health concerns as manifested by at least one of the following:
   1. disproportionate and persistent thoughts about the seriousness of one’s symptoms
   2. persistently high level of anxiety about health or symptoms
   3. excessive time and energy devoted to these symptoms or health concerns
C. although any one somatic symptom may not be continuously present, the state of being symptomatic is persistent (typically >6 mo)
- specify: With predominant pain (previously pain disorder) for those whose somatic symptom is primarily pain
- patients have physical symptoms and believe these symptoms represent the manifestation of a serious illness
- they will persist in this belief despite negative medical investigations and may develop different symptoms over time
- lifetime prevalence may be around 5-7% in the general adult population
- females tend to report more somatic symptoms than males do, cultural factors may influence sex ratio
- complications: anxiety and depression commonly comorbid (up to 80%), unnecessary medications or surgery
- often a misdiagnosis for an insidious illness so rule out all organic illnesses (e.g. multiple sclerosis)
**Illness Anxiety Disorder**

- preoccupation with fear of having, or the idea that one has, a serious disease, to the point of causing significant impairment
- convictions persist despite negative investigations and medical reassurance
- somatic symptoms are mild or not present
- there is a high level of anxiety about health and the individual is easily alarmed about personal health status
- person engages in maladaptive behaviour such as excessive physical checking or total healthcare avoidance
- duration is ≥6 mo; onset in 3rd-4th decade of life
- a new diagnostic entity so epidemiology is not well known; however, it is likely less common than SSD
- possible role for SSRIs due to generally high level of anxiety

**Conversion Disorder**

*(Functional Neurological Symptom Disorder)*

- one or more symptoms or deficits affecting voluntary motor or sensory function that mimic a neurological or GMC (e.g. impaired coordination, local paralysis, double vision, seizures, or convulsions)
- does not need to be preceded by a psychological event as per previous DSM criteria, however this is still worth exploring as many patients will present after such an event or related to a medical diagnosis in a first-degree relative
- 2-5/100,000 in general population; 5% of referrals to neurology clinics
- more common in rural populations and in individuals with little medical knowledge
- spontaneous remission in 95% of acute cases, 50% of chronic cases (>6 mo)
- key to diagnosis is specific neurological testing to detect incompatible findings (e.g. Hoover’s sign, dermatome testing)

**Dissociative Disorders**

**Definition**

- dissociation so severe that the usually integrated functions of consciousness and perception of self break down
- differential diagnosis: PTSD, acute stress disorder, borderline personality disorder, somatization disorder, substance abuse, GMC (various neurologic disorders including complex/partial seizures, migraine, Cotard syndrome)

**Dissociative Identity Disorder**

- disruption of identity characterized by two or more distinct personality states or an experience of possession
- can manifest as sudden alterations in sense of self and agency (ego-dysytonic emotions, behaviours, speech)
- features recurrent episodes of amnesia (declarative or procedural)
Dissociative Amnesia

- inability to recall important autobiographical information, usually of a traumatic or stressful nature, that is inconsistent with normal forgetting. Not attributable to other psychiatric disorder or medical illness
- localized/selective amnesia: failure to recall all/some events during a prescribed period of time
- generalized amnesia: (more rare) complete loss of memory for one’s life history, ± procedural, semantic knowledge. Usually sudden onset. Often will present with perplexity, disorientation, aimless wandering

Depersonalization/Derealization Disorder

- persistent or recurrent episodes of one or both of
  - depersonalization: experiences of detachment from oneself, feelings of unreality, or being an outside observer to one’s thoughts, feelings, speech, and actions (can feature distortions in perception including time, as well as emotional and physical numbing)
  - derealization: experiences of unreality or detachment with respect to the surroundings (e.g. feeling as if in a dream, or that the world is not real, external visual world is foggy or distorted)
- transient (seconds-hours) experiences of this nature are quite common in the general population
- episodes can range from hours-years, patients are often quite distressed and verbalize concern of “going crazy”

Sleep Disorders

- for more information regarding normal sleep cycles and the illnesses described, see Neurology, Sleep Disorders, N48

Overview

- adequate sleep is essential to functioning; deprivation can lead to cognitive impairment and can contribute to death
- circadian rhythms help regulate mood and cognitive performance
- neurotransmitters commonly implicated in psychiatric illnesses also regulate sleep
  - acetylcholine activity and decreased activity of monoamine neurotransmitters is associated with greater REM sleep
  - decreased adrenergic and cholinergic activity are associated with NREM sleep
- depression is associated with decreased delta (deep, slow-wave) sleep, decreased REM latency, and increased REM density
- criteria
  - must cause significant distress or impairment in functioning
  - not due to a GMC or medications/drugs (unless specified)

Management

- pharmacological treatments are illness-specific
  - non-benzodiazepines preferable (e.g. trazodone, zopiclone, quetiapine), but benzodiazepines a short term option
  - medication should not be prescribed without having first made a diagnosis and considering major psychiatric illnesses (major depression and alcohol use disorders are common etiologies)
  - sleep hygiene is a simple, effective but often underutilized method for addressing sleep disturbances. Recommendations include
    - waking up and going to bed at same time every day, including on weekends
    - avoiding long periods of wakefulness in bed
    - not using bed for non-sleep activities (reading, TV, work)
    - avoiding napping
    - discontinuing or reducing consumption of alcohol, caffeine, drugs
    - exercising at least 3-4x per week (but not in the evening, if this interferes with sleep)
Table 8. Major DSM 5 Sleep-Wake Disorders
Note: For more information regarding specific disorders, see: Neurology, Sleep Disorders, N48; Family Medicine, Sleep Disorders, FM48; and Respirology, Sleep Apnea, R31

</tbody>
</table>

Sexuality and Gender

Gender Dysphoria

Definition
- the distress that may coincide with conflict between one’s experienced/expressed gender and one’s assigned gender

Typical Presentation
- strong and persistent cross-gender identification
- desire to be rid of primary/secondary sex characteristics and to gain the primary/secondary sex characteristics of their identified gender
- repeated stated desire or insistence that one is of the opposite sex
- preference for cross-dressing, cross-gender roles in make-believe play
- intense desire to participate in the stereotypical games and pastimes of the opposite sex
- strong preference for playmates of the opposite sex
- significant distress or impairment in functioning and persistent discomfort with his or her sex or gender role

Treatment
- psychotherapy
- hormonal therapy
- sexual reassignment surgery

Paraphilic Disorders

Definition
- intense and persistent sexual interest other than sexual interest in genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners
- paraphilic disorder: paraphilia that causes distress or functional impairment to the individual, or a paraphilia whose realization entails personal harm, or risk of harm to others
• subtypes: voyeuristic, exhibitionistic, frotteuristic, sexual masochism, sexual sadism, pedophilic, fetishes, transvestic, other specified paraphilic disorder, unspecified paraphilic disorder
• rarely self-referred; come to medical attention through interpersonal or legal conflict
• person usually has more than one paraphilia; 5% of paraphilias attributed to women
• typical presentation
• begins in childhood or early adolescence; increasing in complexity and stability with age
• chronic, decreases with advancing age but may increase with stress

Treatment
• anti-androgen drugs
• behaviour modification
• psychotherapy

SEXUAL DYSFUNCTION
• see Gynecology, GY33 and Urology, U30

Eating Disorders

Epidemiology
• anorexia nervosa (AN): 1% of adolescent and young adult females; onset 13-20 yr old
• bulimia nervosa (BN): 2-4% of adolescent and young adult females; onset 16-18 yr old
• F:M=10:1; mortality 5-10%

Etiology
• multifactorial: psychological, sociological, and biological associations
• individual: perfectionism, lack of control in other life areas, history of sexual abuse
• personality: obsessive-compulsive, histrionic, borderline
• familial: maintenance of weight equilibrium and control in dysfunctional family
• cultural factors: prevalent in industrialized societies, idealization of thinness in the media
• genetic factors
  ▪ AN: 6% prevalence in siblings, with one study of twin pairs finding concordance in 9 of 12 monozygotic pairs versus concordance in 1 of 14 dizygotic pairs
  ▪ BN: higher familial incidence of affective disorders than the general population

Risk Factors
• physical factors: obesity, chronic medical illness (e.g. DM)
• psychological factors: individuals who by career choice are expected to be thin, family history (mood disorders, eating disorders, substance abuse), history of sexual abuse (especially for BN), homosexual males, competitive athletes, concurrent associated mental illness (depression, OCD, anxiety disorder [especially panic and agoraphobia], substance abuse [specifically for BN])

Anorexia Nervosa

DSM-5 Diagnostic Criteria for Anorexia Nervosa
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. intake and weight: restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected

B. fear or behaviour: intense fear of gaining weight or of becoming fat, or persistent behaviour that interferes with weight gain, even though at a significantly low weight

C. perception: disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight

• specifiers: partial remission, full remission, severity based on BMI (mild = BMI >17 kg/m², moderate = BMI 16-16.99 kg/m², severe = BMI 15-15.99 kg/m², extreme = BMI <15 kg/m²), type (restricting = during last 3 mo no episodes of binge-eating or purging vs. binge-eating/purging type = in last 3 mo have participated in recurrent episodes of binge-eating/purging)

Management
• psychotherapy: individual, group, family (gold standard): address food and body perception, coping mechanisms, health effects
• medications of little value
• outpatient programs and inpatient programs are available
• inpatient hospitalization for treatment of eating disorders is rarely on an acute basis (unless there is a concurrent psychiatric reason for emergent admission e.g. suicide risk)
• admit to a medical ward for hospitalization: <65% of standard body weight (<85% of standard body weight for adolescents), hypovolemia requiring intravenous fluid, heart rate <40 bpm, abnormal serum chemistry or if actively suicidal
• agree on target body weight on admission and reassure this weight will not be surpassed
• monitor for complications of AN (see Table 9)
• monitor for refeeding syndrome

Athletic Triad
• Disordered eating
• Amenorrhea
• Osteoporosis

Some patients with insulin-dependant DM may stop their insulin in order to lose weight
a potentially life-threatening metabolic response to refeeding in severely malnourished patients resulting in severe shifts in fluid and electrolyte levels
- complications include hypophosphatemia, congestive heart failure, cardiac arrhythmias, delirium, and death
- prevention: slow refeeding, gradual increase in nutrition, supplemental phosphorus, close monitoring of electrolytes and cardiac status

**Prognosis**
- early intervention much more effective (adolescent onset has much better prognosis than adult onset)
- 1 in 10 adolescents continue to have anorexia nervosa as adults
- with treatment, 70% resume a weight of at least 85% of expected levels and about 50% resume normal menstrual function
- eating peculiarities and associated psychiatric symptoms are common and persistent
- long-term mortality: 10-20% of patients hospitalized will die in next 10-30 yr (secondary to severe and chronic starvation, metabolic or cardiac catastrophes, with a significant proportion committing suicide)

### Bulimia Nervosa

**DSM-5 Diagnostic Criteria for Bulimia Nervosa**

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

- **A.** recurrent episodes of binge-eating; an episode of binge-eating is characterized by both of the following
  - eating, in a discrete period of time, an amount of food that is definitely larger than what most individuals would eat during a similar period of time and under similar circumstances
  - a sense of lack of control over eating during the episode
- **B.** recurrent inappropriate compensatory behaviour in order to prevent weight gain, such as self-induced vomiting, misuse of laxatives, diuretics, enemas, or other medications, fasting, or excessive exercise
- **C.** the binge-eating and inappropriate compensatory behaviours both occur, on average, at least once a week for 3 mo
- **D.** self-evaluation is unduly influenced by body shape and weight
- **E.** the disturbance does not occur exclusively during episodes of AN
  - **specifiers:** partial remission, full remission, severity (mild = 1-3 inappropriate compensatory behaviours/wk, moderate = 4-7 inappropriate compensatory behaviours/wk, severe = 8-13 inappropriate compensatory behaviours/wk, extreme = 14+ inappropriate compensatory behaviours/wk)

**Associated Features**
- fatigue and muscle weakness due to repetitive vomiting and fluid/electrolyte imbalance
- tooth decay
- swollen appearance around angle of jaw and puffiness of eye sockets due to fluid retention
- reddened knuckles, Russell's sign (knuckle callus from self-induced vomiting)
- trouble concentrating
- weight fluctuation over time

**Management**
- admission for significant electrolyte abnormalities
- biological: treatment of starvation effects, SSRIs (fluoxetine most evidence) as adjunct
- psychological: develop trusting relationship with therapist to explore personal etiology and triggers, CBT, family therapy, recognition of health risks
- social: challenge destructive societal views of women, use of hospital environment to provide external patterning for normative eating behaviour

**Prognosis**
- relapsing/remitting disease
- good prognostic factors: onset before age 15, achieving a healthy weight within 2 yr of treatment
- poor prognostic factors: later age of onset, previous hospitalizations, individual and familial disturbance
- 60% good treatment outcome, 30% intermediate outcome, 10% poor outcome
### Binge-Eating Disorder

**Definition**
- recurrent episodes of binge-eating (as defined by criteria A of BN) that are associated with eating much more rapidly than normal, eating until feeling uncomfortably full, eating large amounts when not physically hungry, eating alone because embarrassed by how much one is eating, feeling disgusted with oneself/depressed/very guilty afterwards at least once/wk x 3 mo
- not associated with any compensatory behaviours
- dieting usually follows binge-eating (vs. BN where dysfunctional dieting typically precedes binge-eating)
- associated with health consequences (e.g. increased risk of weight gain, obesity)

**Epidemiology**
- F:M = 2:1
- begins in adolescence or young-adulthood

**Treatment**
- hallmark is CBT

### Avoidant/Restrictive Food Intake Disorder

**Definition**
- eating/feeding disturbance to the point that there is persistent failure to meet appropriate nutritional and/or energy needs such that individual experiences significant weight loss/growth failure, have nutritional deficiencies, may become dependent on enteral feeding/oral nutritional supplementation, has a marked interference with psychosocial functioning
  - does not occur during an episode of AN or BN
  - no evidence of distress in the way in which one's body weight or shape is experienced

**Risk Factors**
- temperament (e.g. anxiety disorders), environment (e.g. familial anxiety), genetic (e.g. history of GI conditions)
- begins in infancy and can persist into adulthood

**Treatment**
- watchful waiting
- behaviour modification
- psychotherapy

</tr>
</tbody>
</table>
Personality Disorders

- an evolving personality disorder literature describes that personality is better understood using a trait-based dimensional approach (e.g. 5 major traits such as extraversion, agreeableness, conscientiousness, neuroticism, and openness to experiences rated on a continuum of dysfunctional effects) rather than discrete categories; however, the discrete categories still remain in the current DSM and will be referenced here

General Information
- an enduring pattern of inner experience and behaviour that deviates markedly from the expectations of the individual’s culture; manifested in two or more of: cognition, affect, interpersonal functioning, impulse control
- inflexible and pervasive across a range of situations
- pattern is stable and well established by adolescence or early adulthood (vs. a sudden onset)
- associated with many complications, such as depression, suicide, violence, brief psychotic episodes, multiple drug use, and treatment resistance
- relationship building and establishing boundaries are important; focus should be placed on validating, finding things to be truly empathetic about, and speaking to strengths
- mainstay of treatment is psychotherapy with the addition of pharmacotherapy to treat associated axis I disorders (i.e. depression, anxiety, substance abuse)

Classification
- personality disorders are divided into three clusters (A, B, and C), with shared features among disorders within each

Table 10. Description and Diagnosis of Personality Disorders

<table>
<thead>
<tr>
<th>Cluster A “Mad” Personality Disorders</th>
<th>Cluster B “Odd” Personality Disorders</th>
<th>Cluster C “Deviant” Personality Disorders</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paranoid Personality Disorder (0.5%-3%)</td>
<td>Schizotypal Personality Disorder (3.5-6%)</td>
<td>Schizoid Personality Disorder</td>
</tr>
<tr>
<td>Pervasive distrust and suspiciousness of others, interpret motives as malevolent</td>
<td>Pattern of eccentric behaviours, peculiar thought patterns</td>
<td>Neither desires nor enjoys close relationships including being a part of a family; prefers to be alone</td>
</tr>
<tr>
<td>Blame problems on others and seem angry and hostile</td>
<td>Diagnosis requires 5+ of: ME PECULIAR</td>
<td>Lifelong pattern of social withdrawal</td>
</tr>
<tr>
<td>Diagnosis requires 4+ of: SUSPECT</td>
<td>1. Magical thinking</td>
<td>Seen as eccentric and reclusive with restricted affect</td>
</tr>
<tr>
<td>1. Suspicious that others are exploiting or deceiving them</td>
<td>2. Experiences unusual perceptions (including body illusions)</td>
<td>Diagnosis requires 4 of: DISTANT</td>
</tr>
<tr>
<td>2. Unforgiving (bears grudges)</td>
<td>3. Paranoid ideation</td>
<td>1. Detached/flat affect, emotionally cold</td>
</tr>
<tr>
<td>3. Spousal infidelity suspected without justification</td>
<td>4. Eccentric behaviour or appearance</td>
<td>2. Indifferent to praise or criticism</td>

<td>5. Absence of close friends (other than first-degree relatives)</td>
</tr>
<tr>
<td></td>
<td>9. Anxiety in social situations</td>
<td>7. Takes pleasure in few (if any) activities</td>
</tr>
</tbody>
</table>
### Cluster B “Bad” Personality Disorders

- Patients seem dramatic, emotional, inconsistent
- Familial association with mood disorders
- Common defense mechanisms: denial, acting out, regression (histrionic PD), splitting (borderline PD), projective identification, idealization/devaluation

#### Borderline Personality Disorder (2-4%)

- Unstable moods and behaviour, feel alone in the world, problems with self-image. History of repeated suicide attempts, self-harm behaviours. Inpatients commonly report history of sexual abuse. Tends to fizzle out as patients age. DBT is the principal treatment (see Psychotherapy, PS43).
- **10% suicide rate**

**Diagnosis requires 5+ of:**

<table>
<thead>
<tr>
<th>IMPULSIVE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Impulsive (min. 2 self-damaging ways, e.g. sex/drugs/spending)</td>
</tr>
<tr>
<td>2. Mood/affect instability</td>
</tr>
<tr>
<td>3. Paranoia or dissociation under stress</td>
</tr>
<tr>
<td>4. Unstable self-image</td>
</tr>
<tr>
<td>5. Labile intense relationships</td>
</tr>
<tr>
<td>6. Suicidal gestures / self-harm</td>
</tr>
<tr>
<td>7. Inappropriate anger</td>
</tr>
<tr>
<td>8. Avoiding abandonment (real or imagined, frantic efforts to)</td>
</tr>
<tr>
<td>9. Emptiness (feelings of)</td>
</tr>
</tbody>
</table>

#### Narcissistic Personality Disorder (2%)

- Sense of superiority, needs constant admiration, lacks empathy, but with fragile sense of self.
- Consider themselves “special” and will exploit others for personal gain

**Diagnosis requires 5+ of:**

<table>
<thead>
<tr>
<th>GRANDIOSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Grandiose</td>
</tr>
<tr>
<td>2. Requires excessive admiration</td>
</tr>
<tr>
<td>3. Arrogant</td>
</tr>
<tr>
<td>4. Needs to be special (and associate with other specials)</td>
</tr>
<tr>
<td>5. Dreams of success, power, beauty, love</td>
</tr>
<tr>
<td>6. Interpersonally exploitative</td>
</tr>
<tr>
<td>7. Others (lacks empathy, unable to recognize feelings/needs of)</td>
</tr>
<tr>
<td>8. Sense of entitlement</td>
</tr>
<tr>
<td>9. Envious (or believes others are envious)</td>
</tr>
</tbody>
</table>

#### Antisocial Personality Disorder (M: 3%, F: 1%)

- Lack of remorse for actions, manipulative and deceitful, often violate the law. May appear charming on first impression. Pattern of disregard for others and violation of others’ rights must be present before age 15; however, for the diagnosis of ASPD patients must be at least 18. Strong association with Conduct Disorder, history of trauma/abuse common (see Child Psychiatry).

**Diagnosis requires 5+ of:**

<table>
<thead>
<tr>
<th>CORRUPT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Cannot conform to law</td>
</tr>
<tr>
<td>2. Obligations ignored (irresponsible)</td>
</tr>
<tr>
<td>3. Reckless disregard for safety</td>
</tr>
<tr>
<td>4. Ransomless</td>
</tr>
<tr>
<td>5. Underhanded (deceitful)</td>
</tr>
<tr>
<td>6. Planning insufficient (impulsive)</td>
</tr>
<tr>
<td>7. Temper (irritable and aggressive)</td>
</tr>
</tbody>
</table>

#### Histrionic Personality Disorder (1.3-3%)

- Attention-seeking behaviour and excessively emotional. Are dramatic, flamboyant, and extroverted. Cannot form meaningful relationships. Often sexually inappropriate

**Diagnosis requires 5+ of:**

<table>
<thead>
<tr>
<th>ACTRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Appearance used to attract attention</td>
</tr>
<tr>
<td>2. Center of attention (else uncomfortable)</td>
</tr>
<tr>
<td>3. Theatrical</td>
</tr>
<tr>
<td>4. Relationships (believed to be more intimate than they are)</td>
</tr>
<tr>
<td>5. Easily influenced</td>
</tr>
<tr>
<td>6. Seductive behaviour</td>
</tr>
<tr>
<td>7. Shallow expression of emotions (which rapidly shift)</td>
</tr>
<tr>
<td>8. Speech (impressionistic and vague)</td>
</tr>
</tbody>
</table>

#### Cluster C “Sad”

- Patients seem anxious, fearful
- Familial association with anxiety disorder
- Common defense mechanisms: isolation, avoidance, hypochondriasis

#### Avoidant Personality Disorder (0.5-1.6%)

- Timid and socially awkward with a pervasive sense of inadequacy and fear of criticism. Fear of embarrassing or humiliating themselves in social situations so remain withdrawn and socially inhibited

**Diagnosis requires 4+ of:**

<table>
<thead>
<tr>
<th>CRINGES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Criticism or rejection preoccupies thoughts in social situations</td>
</tr>
<tr>
<td>2. Restrained in relationships due to fear of being harmed</td>
</tr>
<tr>
<td>3. Inhibited in new relationships due to fear of inadequacy</td>
</tr>
<tr>
<td>4. Needs to be sure of being liked before engaging socially</td>
</tr>
<tr>
<td>5. Gets around occupational activities requiring interpersonal contact</td>
</tr>
<tr>
<td>6. Embarrassment prevents new activity or taking risks</td>
</tr>
<tr>
<td>7. Self-viewed as unappealing or inferior</td>
</tr>
</tbody>
</table>

#### Obsessive-Compulsive Personality Disorder (3-10%)

- Preoccupation with orderliness, perfectionism, and mental and interpersonal control. Is inflexible, closed-off, and inefficient

**Diagnosis requires 4+ of:**

<table>
<thead>
<tr>
<th>SCRIMPER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Stubborn</td>
</tr>
<tr>
<td>2. Cannot discard worthless objects</td>
</tr>
<tr>
<td>3. Rule/detox obsessed (to point of activity lost)</td>
</tr>
<tr>
<td>4. Inflexible in matters of morality, ethics, values</td>
</tr>
<tr>
<td>5. Miserly</td>
</tr>
<tr>
<td>6. Perfectionistic</td>
</tr>
<tr>
<td>7. Excludes leisure due to devotion to work</td>
</tr>
<tr>
<td>8. Reluctant to delegate to others</td>
</tr>
</tbody>
</table>

#### Dependent Personality Disorder (1.5-6.7%)

- Pervasive and excessive need to be taken care of, excessive fear of separation, clinging and submissive behaviours. Difficulty making everyday decisions. Useful to set regulated treatment schedule (regular, brief visits) and being firm about in between issues. Encourage patient to do more for themselves, engage in own problem-solving

**Diagnosis requires 5+ of:**

<table>
<thead>
<tr>
<th>RELIANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Reassurance required for everyday decisions</td>
</tr>
<tr>
<td>2. Expressing disagreement difficult</td>

Child Psychiatry

Developmental Concepts

- **temperament**: innate psycho-physiological and behavioural characteristics of a child (e.g. emotionality, activity, and sociability); spectrum from “difficult” to “slow-to-warm-up” to “easy temperament”
- **parental fit**: the congruence between parenting style (authoritative, authoritarian, permissive) and child’s temperament
- **attachment**: special relationship between child and primary caretaker(s); develops during first year, best predictor of a child’s attachment style is their parent’s attachment style
- **separation anxiety** (normal between 10-18 mo): separation from attachment figure results in distress

Table 12. Attachment Models

</tbody>
</table>

Mood Disorders

MAJOR DEPRESSIVE DISORDER

Epidemiology

- pre-pubertal 1-2% (no gender differences); post-pubertal 4-18% (F:M = 2:1)

Clinical Presentation

- see Mood Disorders, PS9
- only difference in diagnostic criteria is that irritable mood may replace depressed mood
- physical factors: insomnia (children), hypersomnia (adolescents), somatic complaints, substance abuse, decreased hygiene
- psychological factors: irritability, boredom, anhedonia, low self-esteem, deterioration in academic performance, social withdrawal, lack of motivation, listlessness
- comorbid diagnoses of anxiety, ADHD, ODD, conduct disorder, and eating disorders

Treatment

- majority never seek treatment
- individual (CBT, IPT)/family therapy and education, modified school program
- SSRIs (strongest evidence for fluoxetine 10-40mg/d)
- close follow-up on adolescents starting SSRIs to monitor for increased suicidal ideation or behaviour
- in severe depression, best evidence for combined pharmacotherapy and psychotherapy
- ECT: only in adolescents who have severe illness, psychotic features, catatonic features, persistently suicidal
- light therapy, self-help books
**Prognosis**
- prolonged episodes, up to 1-2 yr
- adolescent onset predicts chronic mood disorder; up to 2/3 will have another depressive episode within 5 yr
- complications
- negative impact on family and peer relationships
- school failure
- significantly increased risk of suicide attempt (10%) or completion (however, suicide risk low for pre-pubertal children)
- substance abuse

**DISRUPTIVE MOOD DYSREGULATION DISORDER**

**Clinical Presentation**
- severe, developmentally inappropriate, recurrent verbal or behavioural temper outbursts at least 3 times per wk
- mood is predominantly irritable or angry in between outbursts, as observable by others
- these symptoms occur before 10 y, have been occurring for 12 mo, with no more than 3 consecutive mo free from symptoms
- high rates of comorbidities; ADHD, ODD, anxiety disorders, depressive disorders

**BIPOLAR DISORDER**

**Clinical Presentation**
- see *Bipolar Disorder, PS13*
- mixed presentation and psychotic symptoms (hallucinations and delusions) more common in adolescent population than adult population
- unipolar depression may be an early sign of adult bipolar disorder
- ~30% of psychotic depressed adolescents receive a bipolar diagnosis within 2 yr of presentation
- associated with rapid onset of depression, psychomotor retardation, mood-congruent psychosis, affective illness in family, pharmacologically-induced mania

**Treatment**
- Pharmacotherapy: mood stabilizers and/or antipsychotics
- Psychotherapy: CBT, Family Focused Therapy

---

**Anxiety Disorders**

- lifetime prevalence 10-20%; F:M = 2:1

**Clinical Presentation**
- children and adolescents rarely vocalize their anxiety but instead demonstrate it through their behaviour
- school problems, recurrent physical symptoms (abdominal pain, headaches) especially in mornings, social and relationship problems, social withdrawal and isolation, family conflict, difficulty with sleep initiation, irritability and mood symptoms, alcohol and drug use in adolescent

**Differential Diagnosis**
- clinical judgment important to differentiate developmentally normal from pathological anxiety
- for school avoidance, differentiate fear of general performance, humiliation, worry about separation and rule out bullying and school refusal due to learning disorder
- depressive disorders, ODD, truancy

**Course and Prognosis**
- better prognosis with later age of onset, lower co-morbidities, early initiation of treatment, ability to maintain school attendance and peer relationships, absence of social anxiety disorder
- with treatment up to 80% of children will not meet criteria for their anxiety disorder at 3 year follow-up but up to 30% will meet criteria for another psychiatric disorder

**Treatment**
- similar principles for most childhood anxiety disorders due to overlapping symptomatology and frequent comorbidity
- family psychotherapy, predictive and supportive environment
- CBT: child and parental education, relaxation techniques (e.g. deep breathing), exposure/desensitization, recognizing and correcting anxious thoughts
- pharmacotherapy: SSRIs (e.g. fluoxetine, paroxetine), benzodiazepines (alprazolam, clonazepam have evidence – use with caution due to addictive and abuse potential as well as disinhibiting effect, especially in neurodevelopmental delay)
  - fluvoxamine and sertraline also have good evidence, particularly for OCD
SEPARATION ANXIETY DISORDER
- excessive and developmentally inappropriate anxiety on real, threatened or imagined separation from primary caregiver or home with physical or emotional distress for at least 4 wk
- school refusal (75%)
- persistent worry, refusal to sleep alone, clinging, nightmares involving separation, somatic symptoms
- comorbid major depression common (2/3)
- worry about something happening to parent or themselves if separated

SOCIAL PHOBIA (SOCIAL ANXIETY DISORDER)
- situations in which the child feels they are exposed to scrutiny by others can provoke anxiety and become feared or avoided
- must distinguish between shy child, child with issues functioning socially (e.g. autism), and child with social anxiety
  - diagnosis only if anxiety interferes significantly with daily routine, social life, academic functioning or if markedly distressed. Must occur in settings with peers, not just adults
  - features: temper tantrums, freezing, clinging behaviour, mutism, excessively timid, stays on periphery, refuses to be involved in group play
  - significant implication for future quality of life if untreated; lower levels of satisfaction in leisure activities, higher rates of school dropout, poor workplace performance, increased rates of remaining single

SELECTIVE MUTISM
- consistent failure to speak in specific social situations in which there is an expectation for speaking despite speaking in other situations
- the disturbance interferes with educational or occupational achievement or with social communication

GENERALIZED ANXIETY DISORDER
- diagnostic criteria same as adults (see Generalized Anxiety Disorder, PS16)
  - note: only 1 item is required in children for Criteria C
- often redo tasks, show dissatisfaction with their work, and tend to be perfectionistic
- often fearful in multiple settings and expect more negative outcomes when faced with academic or social challenges, and require reassurance and support to take on new tasks

SPECIFIC PHOBIA
- common phobias in childhood include a fear of heights, small animals, doctors, dentists, darkness, loud noises, thunder and lightning

Neurodevelopmental Disorders

Autism Spectrum Disorder

Diagnosis
- persistent deficits in social communication and interaction, manifested in three areas
  - social-emotional reciprocity, ranging, for example, from abnormal social approach and failure of normal back-and-forth conversation, to reduced sharing of interests, emotions, or affect, to failure to initiate or respond to social interactions
  - nonverbal communicative behaviours, ranging, for example, from poorly integrated verbal and nonverbal communication, to abnormalities in eye contact and body language or deficits in understanding and use of gestures, to a total lack of facial expressions and nonverbal communication
  - developing, maintaining, and understanding relationships, ranging, for example, from difficulties adjusting behaviour to suit various social contexts, to difficulties in sharing imaginative play or in making friends, to absence of interest in peers
- restricted, repetitive patterns of behaviour, interests, or activities. Two or more of: stereotyped or repetitive motor movements, insistence on sameness, highly restricted fixed interests, hyper-/ hypo-reactivity to sensory input
- symptoms must be present in early developmental period
- symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning
- not better explained by intellectual disability or global developmental delay
- specifiers
  - current severity: requiring very substantial support, requiring substantial support, requiring support
  - with or without accompanying language impairment
  - with or without accompanying intellectual impairment
  - associated with known medical or genetic condition or environmental factors (i.e. Rett’s disorder)

Differential Diagnosis
- developmental disability, childhood schizophrenia, social phobia, OCD, communication disorder, non-verbal learning disorder, ADHD, abuse, hearing or visual impairment, seizure disorder, motor impairment

Management
- hearing and vision test to rule out impairment
- psychological testing to assess intellectual functioning and learning
- chromosomal analysis to rule out abnormalities (e.g. Trisomy 21, Fragile X syndrome)
- rule out psychotic disorders, social problems, depression, anxiety, abuse

Treatment
- team-based: school, psychologist, occupational therapist, physiotherapist, speech and language therapy, pediatrics, psychiatry
- psychosocial: family education and support, school programming, behaviour management, social skills training
- treat concomitant disorders such as ADHD, tics, OCD, anxiety, depression, and seizure disorder
- pharmacotherapy: atypical antipsychotics (for irritability, aggression, agitation, self-mutilation, tics), SSRIs (for anxiety, depression), stimulants (for associated inattention and hyperactivity)

Prognosis
- variable, but improves with early intervention
- better if IQ >60 and able to communicate

Attention Deficit Hyperactivity Disorder
- prevalence: 5-12% of school-aged children; M:F = 4:1, although girls may be under-diagnosed
- girls tend to have inattentive/distractible symptoms; boys have impulsive/hyperactive symptoms

Etiology
- genetic: 75% heritability, dopamine candidate genes DAT1, DRD4
- neurobiology: decreased catecholamine transmission, low prefrontal cortex (PFC) activity, increased beta activity on EEG
- cognitive: developmental disability, poor inhibitory control and other errors of executive function

Diagnosis
- differential: learning disorders, hearing/visual defects, thyroid, atopic conditions, congenital problems (fetal alcohol syndrome, Fragile X), lead poisoning, history of head injury, traumatic life events (abuse)
- diagnosis (3 subtypes)
  - combined type: 6 or more symptoms of inattention and 6 or more symptoms of hyperactivity-impulsivity
  - predominantly inattentive type: 6 or more symptoms of inattention
  - predominantly hyperactive-impulsive type: 6 or more symptoms of hyperactivity-impulsivity
- for older adolescents (>17 yr) or adults, 5 symptoms required
- symptoms persist for >6 mo
- onset before age 12
- symptoms present in at least two settings (i.e. home, school, work)
- interferes with academic, family, and social functioning
- does not occur exclusively during the course of another psychiatric disorder

Observe child for “ATTENTION” features
- Annoying
- Temperamental
- Energetic
- Noisy
- Task incompletion
- Inattentive
- Oppositional
- Negativism

</table>

Features
- difficult to differentiate from highly variable normative behaviour before age 4
- often identified upon school entry
- rule out developmental delay, sensory impairments, genetic syndromes, encephalopathies or toxins (alcohol, lead)
- risk of substance abuse, depression, anxiety, academic failure, poor social skills, risk of comorbid CD and/or ODD, risk of adult ASPD
- associated with family history of ADHD, difficult temperamental characteristics

Treatment
- non-pharmacological: parent management, anger control strategies, positive reinforcement, social skills training, individual/family therapy, behaviour therapy, tutors, classroom intervention, exercise routines, extracurricular activities, omega-3 fatty acids
- pharmacological
  - first line: stimulants (methylphenidate, amphetamine salts)
  - second line: atomoxetine
  - third line/adjunct: nonstimulants (a-agonists; clonidine, guanfacine, NDRI; bupropion)
- for comorbid symptoms: antidepressants, antipsychotics

Prognosis
- 70-80% continue into adolescence, but hyperactive symptoms usually abate
- 65% continue into adulthood; secondary personality disorders and compensatory anxiety disorders are identifiable

Disruptive, Impulse Control, and Conduct Disorder

Oppositional Defiant Disorder

- prevalence: 2-16%, M=F after puberty

Diagnosis
- pattern of negativistic/hostile and defiant behaviour for ≥6 mo with ≥4 of
  - angry/irritable mood: easily loses temper, touchy or easily annoyed, often angry and resentful
  - argumentative/defiant: argues with adults/authority figure, defies requests/rules, deliberately annoys, blames others for their own mistakes or misbehaviour
  - vindictiveness: spiteful or vindictive twice in past 6 mo
- behaviour causes significant impairment in social, academic, or occupational functioning
- behaviours do not occur exclusively during the course of a psychotic or mood disorder
- criteria not met for conduct disorder (CD); if 18 yr or older, criteria not met for ASPD
- may progress to CD, differentiated by an absence of destructive or physically aggressive behaviour
- features that typically differentiate ODD from transient developmental stage: onset <8 yr, chronic duration (>6 mo), frequent intrusive behaviour
- impact of ODD: poor school performance, few friends, strained parent/child relationships, risk of later mood disorders

Treatment
- parent: management training, psychoeducation and family therapy to reduce punitive parenting and parent-child conflict
- behavioural therapy: to teach, practice and reinforce prosocial behaviour
- social: school/day-care interventions
- pharmacotherapy for comorbid disorders
Conduct Disorder

- prevalence: 1.5-3.4% (M:F = 4-12:1)

Etiology
- parental/familial factors: parental psychopathology (e.g. ASPD, substance abuse), child-rearing practices (e.g. child abuse, discipline), low socioeconomic status (SES), family violence
- child factors: difficult temperament, ODD, learning problems, neurobiology

Diagnosis
- differential: ADHD, depression, head injury, substance abuse
- diagnosis: use multiple sources (Achenbach Child Behavioural Checklist, Teacher's Report Form)
  - pattern of behaviour that violates rights of others and age appropriate social norms with ≥3 criteria noted in past 12 mo and ≥1 in past 6 mo
  - aggression to people and animals: bullying, initiating physical fights, use of weapons, forced sex, cruel to people, cruel to animals, stolen while confronting a person (e.g. armed robbery)
  - destruction of property: fire setting with intent to damage, deliberately destroying others’ property
  - deceitfulness or theft: breaking and entering, conning others, stealing nontrivial items without confrontation
  - violation of rules: out all night before age 13, often truant from school before age 13, runaway ≥2 times at least overnight or for long periods of time
- disturbance causes clinically significant impairment in social, academic, or occupational functioning
- if individual is 18 yr or older, criteria not met for ASPD
- diagnostic types
  - childhood onset: at least one criterion prior to age 10
  - poor prognosis: associated with ODD, aggressiveness, impulsiveness
  - adolescent onset: absence of any criteria until age 10
  - better prognosis; least aggressive, gang-related delinquency
  - mild, moderate, severe

Treatment
- early intervention necessary and more effective; long-term follow-up required
- psychosocial: parent management training, anger replacement training, CBT, family therapy, education/employment programs, social skills training,
- pharmacotherapy: for comorbid disorders

Prognosis
- poor prognostic indicators include early-age onset, high frequency, variety of behaviours, pervasiveness (i.e. in home, school, community), comorbid ADHD, early sexual activity, substance abuse
- 50% of CD children become adult ASPD

Intermittent Explosive Disorder

Diagnosis
- recurrent behavioural outbursts representing a failure to control aggressive impulses in children > 6 yr, manifested as either
  - verbal or physical aggression that does not damage others or property, occurring 2+ times per wk for 3 mo
  - 3 outbursts involving physical damage to another person, animal or piece of property in the last 12 mo
- outbursts are out of proportion to triggers or provocation, are not premeditated, and not for primary gain
- outbursts cause clinically significant impairment in social, academic, or occupational functioning

See Pediatrics
- Child Abuse, P14
- Chronic Abdominal Pain, P40
- Developmental Delay, P22
- Intellectual Disability, P23
- Learning Disabilities, P24
- Sleep Disturbances, P13

See Neurology
- Tic Disorders, N34
- Tourette’s Syndrome, N35
Psychotherapy

- treatment in which a person with mental or physical difficulties aims to achieve symptomatic relief through talks with another person
- psychotherapy is delivered by a specially trained social worker, nurse, psychologist, psychiatrist, counselor or general practitioner
- various types of therapy exist because of diverse theories of human psychology and mental illness etiology

Common Factors of Psychotherapy

- good evidence that effective psychotherapy creates observable changes in brain circuitry and connectivity, similar to those observed with successful pharmacologic and other treatment modalities
- studies suggest that up to 30-70% of therapy outcome is due to common factors with only 10-40% from specific factors
- common factors: warmth (unconditional positive regard), accurate empathy, genuineness, goodness of fit

Table 14. Summary of Psychotherapeutic Modalities

<table>
<thead>
<tr>
<th>Type</th>
<th>Indications</th>
<th>Approach, Technique and Theory</th>
<th>Ideal Candidates</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Psychoanalytic/psychodynamic</td>
<td>Psychoneuroses; anxiety, obsessional thinking, compulsive or conversion disorders, sexual dysfunction, depressive states</td>
<td>Theory: Exploration of meaning of early experiences and how they affect emotions and patterns of behaviour. Recollection (remembering), repetition (relying on the analyst), working through (gaining insight) Techniques: free association, dream interpretation, transference analysis</td>
<td>Psychologically minded, highly motivated, wish to understand selves and not just relieve symptoms Able to withstand difficult emotions without fleeing or self-destructive acts High level of function</td>
<td>Time intensive: 12-20 wk for 3-7 yr Psychodynamically oriented therapy: 2-3 times/wk for fewer years</td>
</tr>
<tr>
<td>Supportive</td>
<td>Adjustment disorders, psychosomatic disorders, severe psychotic or personality disorders</td>
<td>Ameliorate symptoms through behavioural or environmental restructuring to aid adaptation and facilitate coping Help patients feel safe, secure and encouraged</td>
<td>Individuals in crisis or with severe symptoms in acute or chronic settings Low insight, low motivation, &quot;weak&quot; ego systems Variable (single session to years, though often short-intermittent)</td>
<td>12-20 wk</td>
</tr>
<tr>
<td>Interpersonal</td>
<td>Mood disorders, bulimia nervosa</td>
<td>Focuses on how interpersonal relationships impact symptoms 4 key problem areas addressed: grief and loss, role transitions, conflict, interpersonal deficits Break the interpersonal cycle: depression, self-esteem, social withdrawal</td>
<td>Individuals with depression or bipolar disorder with some insight and difficult social functioning Absence of severe psychotic process, personality disorder or comorbid substance abuse 12-20 wk</td>
<td>Usually short term (weeks-months)</td>
</tr>
<tr>
<td>Behavioural</td>
<td>Most mental health disorders benefit from specific application of behavioural therapy (e.g. behavioural activation for depression; exposure therapy for phobias; contingency management for anorexia nervosa, substance use disorder)</td>
<td>Systematic Desensitization: mastering anxiety-provoking situations by approaching them gradually and in a relaxed state that limits anxiety Flooding: confronting feared stimulus for prolonged periods until it is no longer frightening Positive Reinforcement: strengthening behaviour and causing it to occur more frequently by rewarding it Negative Reinforcement: causing behaviour to occur more frequently by removing a noxious stimulus when desired behaviour occurs Extinction: causing a behaviour to diminish by not rewarding it Punishment (aversion therapy): causing a behaviour to diminish by applying a noxious stimulus</td>
<td>Individuals with motivation to change and specific symptoms that are amenable to change Global areas of dysfunction such as personality disorder are difficult to treat with behavioural therapy Usually short term (weeks-months)</td>
<td>12-20 wk</td>
</tr>
<tr>
<td>Cognitive Therapy</td>
<td>Depression, anxiety, panic disorder, personality disorders, and somatoform disorders</td>
<td>Moods/emotions are influenced by one’s thoughts and psychiatric disturbances are often caused by habitual errors in thinking With therapy, help patient make explicit their inaccurate automatic thoughts and correct assumptions with a more balanced perspective Uses thought records (often charts with column headings including “situation,” “feeling,” “thought,” “cognitive distortion”) to help monitor thoughts, the situations they occur in, and the feelings they might provoke due to their underlying cognitive errors</td>
<td>Motivated patients who will comply with homework, openness to changing core beliefs First course - usually 15 - 25 weeks Maintenance therapy can be carried out over years</td>
<td>First course - usually 15 - 25 weeks Maintenance therapy can be carried out over years</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Indications</th>
<th>Approach, Technique and Theory</th>
<th>Ideal Candidates</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cognitive Behavioural Therapy</td>
<td>Most mental health disorders including: mood, anxiety, OCD, personality, eating, substance use, psychotic disorders</td>
<td>Combines theory and method from Cognitive and Behavioural therapies to teach the patient to change connections between thinking patterns, habitual behaviours and mood/anxiety problems</td>
<td>Individuals with motivation to change and are able to participate in homework</td>
<td>Typically 6-18, 1hr sessions Maintenance sessions can be added over time</td>
</tr>
<tr>
<td>Dialectical Behavioural Therapy</td>
<td>Borderline Personality Disorder</td>
<td>Therapy that combines CBT techniques with Buddhist Zen mindfulness practices and dialectical philosophy Focusses on 4 types of skills: mindfulness, emotion regulation, interpersonal effectiveness, and distress tolerance Involves 4 components: individual therapy, group skills training, phone consultations, and a consultation team</td>
<td>Patients with severe problems of emotional dysregulation, impulsivity, and self-harm Patients with borderline personality disorder or borderline personality traits</td>
<td>Typically 1 yr</td>
</tr>
<tr>
<td>Motivational Interviewing</td>
<td>Substance use disorders Techniques can be applied to facilitate behavioural change in most psychological problems</td>
<td>Spirit of MI (CAPE): Compassion, Acceptance, Partnership,Evocation Principles of MI (RULE): Resist “righting reflex”, Understand client and their reasons for change, Listen, Empower by conveying hope and supporting autonomy Techniques of MI (DARS): Open-ended questions, Affirmations to validate client, Reflections (the skill of accurate empathy), Summaries to help client organize self</td>
<td>Patients with problematic substance use, maladaptive behaviour patterns (therapy disengagement, medication noncompliance, poor health habits)</td>
<td>Brief interventions (efficacy with as little as 15 min, single sessions), better result with more sessions, Addiction is a chronic condition, often need boosters over time</td>
</tr>
<tr>
<td>Motivational Enhancement Therapy (MET)</td>
<td></td>
<td></td>
<td></td>
<td>MET = 4 sessions</td>
</tr>
</tbody>
</table>

Other Therapies

- group psychotherapy
  - aims to promote self-understanding, acceptance, social skills
- family therapy
  - family system considered more influential than individual especially for children
  - focus on here and now, re-establishing parental authority, strengthening normal boundaries, and rearranging alliances
- narrative psychotherapy
  - an integrative approach that attempts to understand the patients experience as a whole
- hypnosis: mixed evidence for the treatment of pain, phobias, anxiety, and smoking cessation
  - mindfulness-based cognitive therapy (MBCT)/stress reduction (MBSR): derived from Buddhist meditative and philosophical practices; aims to help people attend to thoughts, behaviours and emotions non-judgmentally and in the moment using guided breathing exercises exercising evidence for adjustment disorder, MDD, anxiety, pain disorders, insomnia, substance relapse prevention

Pharmacotherapy

Antipsychotics

- “antipsychotics” and “neuroleptics” are terms used interchangeably
- overall mechanism of action: block, to varying degrees, dopamine activity in target brain pathways (see sidebar)
- indications: for calm, sleep, psychosis and mania reduction, mood stabilizing - used in schizophrenia and other psychotic disorders, mood disorders with or without psychosis, violent behaviour, autism, Tourette’s, somatoform disorders, dementia, OCD
- onset: immediate calming effect and decrease in agitation; thought disorder responds in 2-4 wk
- rational use
  - no reason to combine antipsychotics
  - choosing an antipsychotic
    - all antipsychotics are equally effective, except for clozapine (considered to be most effective in treatment-refractory psychoses)
    - atypical antipsychotics (SGA) are as effective as typical (first generation) antipsychotics but are thought to have better side effect profiles
    - choose a drug that the patient has responded to in the past or that was used successfully in a family member
- route: PO, short-acting or long-acting depot IM injections, sublingual
- if no response in 4-6 weeks, switch drugs; if response, titrate dose
- duration: minimum 6 mo, usually for life

Dopamine Pathways Affected by Antipsychotics

</tbody>
</table>
Long-Acting Preparations
- antipsychotics formulated in oil for IM injection (see Table 15)
- received on an outpatient basis
- indications: individuals with schizophrenia or other chronic psychosis who relapse because of non-adherence
- dosing: start at low dosages, then titrate every 2 to 4 wk to maximize safety and minimize side effects
- should be exposed to oral form prior to first injection
- side effects: risk of EPS, parkinsonism, increased risk of NMS

Canadian Guidelines for the Treatment of Acute Psychosis in the Emergency Setting
- haloperidol 5 mg IM (or loxapine 25 mg) ± lorazepam 2 mg IM
- olanzapine 2.5-10 mg (PO, IM, quick dissolve)
- risperidone 2 mg (M-tab, liquid)

<tr>
<td>Block serotonin receptors (5-HT2) on presynaptic dopaminergic terminals, triggering dopamine release, and reversing dopamine blockade in some pathways</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Pros
- Inexpensive
- Plenty of injectable forms available
- Fewer EPS
- Low risk of tardive syndromes
- Mood stabilizing effects

Cons
- More EPS
- Tardive syndromes in long-term use
- Not mood stabilizing
- Expensive
- Few injectable forms available
- Metabolic side effects (weight gain, hyperglycemia, lipid abnormalities, metabolic syndrome)
- Extravagant (or new onset) of obsessive behaviour

Effectiveness of Antipsychotic Drugs in Patients with Chronic Schizophrenia

*NEJM* 2005;353:1209-23

**Study:** Randomized, double-blind, active-control trial with median follow-up of 6 mo.

**Patients:** 1,432 patients with a diagnosis of schizophrenia (as per DSM-IV criteria) and able to take antipsychotic medications (as determined by study doctors). Mean age 41, 74% male, 26% female.

**Intervention:** 1-4 capsules daily of olanzapine (20.1 mg), quetiapine (45.3 mg), risperidone (3.9 mg), perphenazine (20.8 mg), or ziprasidone (11.2 mg), with dosage at the discretion of the study doctor. Mean modal doses in parentheses.

**Main Outcome:** Discontinuation of treatment for any cause.

**Results:** Olanzapine group had statistically significant lower rate of discontinuation for any cause (44%) from all others (quetiapine – 82%, risperidone – 74%, perphenazine – 75%, ziprasidone – 79%). There were no significant differences in time until discontinuation due to intolerable side effects; however, olanzapine was associated with a significantly higher rate of metabolic side effects.
### Table 16. Commonly Used Atypical Antipsychotics

<table>
<thead>
<tr>
<th>Antipsychotic</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Risperidone (Risperdal&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Lower incidence of EPS than typical antipsychotics at lower doses (&lt;8 mg)</td>
<td>SE: insomnia, agitation, EPS, H/A, anxiety, prolactin, postural hypotension, constipation, dizziness, weight gain</td>
<td>Quick dissolve (IM-formulations available)</td>
</tr>
<tr>
<td>Olanzapine (Zyprexa&lt;sup&gt;®&lt;/sup&gt;, Zydis&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Better overall efficacy compared to haloperidol</td>
<td>SE: mild sedation, insomnia, dizziness, minimal anticholinergic, early AST and ALT elevation, restlessness, high risk of metabolic effects (weight gain, DM, hyperlipidemia)</td>
<td>Quick dissolve formulation (Zydis&lt;sup&gt;®&lt;/sup&gt;) used commonly in ER setting for better compliance IM form available</td>
</tr>
<tr>
<td>Quetiapine (Seroquel&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Associated with less weight gain compared to clozapine and olanzapine</td>
<td>SE: H/A, sedation, dizziness, constipation</td>
<td>Weekly blood counts for at least 1 mo, then q2wk</td>
</tr>
<tr>
<td>Clozapine (Clozaril®)</td>
<td>Most effective for treatment-resistant schizophrenia</td>
<td>Most sedating of first line atypicals</td>
<td>Do not use with drugs which may cause bone marrow suppression due to risk of agranulocytosis</td>
</tr>
<tr>
<td>Aripiprazole (Abilify&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Less weight gain and risk of metabolic syndrome compared to olanzapine and a lower incidence of EPS compared to haloperidol</td>
<td>SE: H/A, agitation, anxiety, insomnia, weight gain, decreased serum prolactin levels</td>
<td>Weekly blood counts for at least 1 mo, then q2wk</td>
</tr>
</tbody>
</table>

<tr>
<td>Endocrine</td>
<td>Metabolic syndrome</td>
</tr>
</tbody>
</table>

#### Neuroleptic Malignant Syndrome

- **psychiatric emergency**
  - due to massive dopamine blockade; increased incidence with high potency and depot neuroleptics
- **risk factors**
  - medication factors: sudden increase in dosage, starting a new drug
  - patient factors: medical illness, dehydration, exhaustion, poor nutrition, external heat load, male, young adults
- **clinical presentation**
  - mental status changes (usually occur first), fever, autonomic reactivity, rigidity
  - develops over 24-72 h
  - labs: increased creatine phosphokinase, leukocytosis, myoglobinuria
- **treatment**: supportive - discontinue drug, hydration, cooling blankets, dantrolene (hydrantoin derivative, used as a muscle relaxant), bromocriptine (DA agonist)
- **mortality**: 5%

#### Extrapyramidal Symptoms

- incidence related to increased dose and potency
- acute (early-onset; reversible) vs. tardive (late-onset; often irreversible)
Table 18. Extrapyramidal Symptoms

<table>
<thead>
<tr>
<th>Risk Group</th>
<th>Presentation</th>
<th>Onset</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute: Young Asian and Black males</td>
<td>Sustained abnormal posture; torsions, twisting, contraction of muscle groups; muscle spasms (e.g. oculogyric crisis, laryngospasm, torticollis)</td>
<td>Acute: within 5 d</td>
<td>Acute: benzotropine or diphenhydramine</td>
</tr>
<tr>
<td>Elderly females</td>
<td>Motor restlessness; crawling sensation in legs relieved by walking; very distressing, increased risk of suicide and poor adherence</td>
<td>Acute: within 10 d</td>
<td>Acute: bromazepam, propranolol, or diphenhydramine; reduce or change neuroleptic to lower potency</td>
</tr>
<tr>
<td>Elderly females</td>
<td>Tremor, rigidity (cogwheeling); akinesia; postural instability (increased/absent arm-swing, stooped posture, shuffling gait, difficulty pivoting)</td>
<td>Acute: &gt;90 d</td>
<td>Acute: benzotropine (or benzodiazepine if side effects); reduce or change neuroleptic to lower potency</td>
</tr>
<tr>
<td>If third episode, elderly, psychotic features, refractory depression, &gt;2 episodes in 5 yr</td>
<td>Purposeless, constant movements, involving facial and mouth musculature, or less commonly – the limbs</td>
<td>Tardive: &gt;90 d</td>
<td>Tardive: no good treatment; may try clozapine; discontinue drug or reduce dose</td>
</tr>
</tbody>
</table>

Antiparkinsonian Agents (Anticholinergic Agents)

- **types**
  - benztropine (Cogentin®) 2 mg PO, IM or IV OD (~1-6 mg)
  - amantadine (Symmetrel®) 100 mg PO bid (100-400 mg)
  - diphenhydramine (Benadryl®) 25-50 mg PO/IM qid
  - amantadine (Symmetrel®) 100 mg PO bid (100-400 mg)

- do not always prescribe with neuroleptics
- give antiparkinsonian agents only if at high risk for acute EPS or if acute EPS develops
- do not give these for tardive syndromes because they worsen the condition

Antidepressants

- **onset of effect**
  - relief of neurovegetative (physical) symptoms: 1-3 wk
  - relief of emotional/cognitive symptoms: 2-6 wk

- taper TCAs slowly (over weeks-months) because they can cause withdrawal reactions
- tapering of any kind of antidepressant is usually required and based on the half-life of the medication and the patient's individual sensitivity (e.g. fluoxetine does not require a slow taper due to long half life)

- it is important to be particularly vigilant over the first 2 wk of therapy as neurovegetative symptoms may start to resolve while emotional and cognitive symptoms may not (patients may be particularly at risk for suicidal behaviour during this time; in children/adolescents, paroxetine and venlafaxine not prescribed for this reason, as increases restlessness and suicidal ideation)

- treatment of bipolar depression
  - monotherapy with antidepressants is not advisable as a switch from depression to mania can occur
  - patients with bipolar disorder should only be treated with an antidepressant if it is combined with a mood stabilizer or antipsychotic

Table 19. Common Antidepressants

<td>40</td>
<td>40-60</td>
<td>No significant difference when choosing.</td>
</tr>
<tr>
<td>NDRI</td>
<td>bupropion (Wellbutrin®)</td>
<td>100</td>
<td>300-450</td>
<td>Useful for depression, seasonal depression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Causes less sexual dysfunction (may reverse effects of SSRIs/SNRIs), weight gain, and sedation</td>
</tr>
<tr>
<td>TCA (3rd Amines)</td>
<td>amitriptyline (Elavil®)</td>
<td>75-100</td>
<td>150-300</td>
<td>Use for OCD (clomipramine), melancholic depression</td>
</tr>
<tr>
<td></td>
<td>imipramine (Tofran®)</td>
<td>75-100</td>
<td>150-300</td>
<td>Contraindicated with history of seizure, stroke brain tumour, brain injury, closed head injury</td>
</tr>
<tr>
<td>TCA (2nd Amines)</td>
<td>nortriptyline (Aventyl®)</td>
<td>75-100</td>
<td>75-150</td>
<td>Not recommended for anxiety disorder treatment because of stimulating effects</td>
</tr>
<tr>
<td></td>
<td>desipramine (Norpramin®)</td>
<td>100-200</td>
<td>150-300</td>
<td>Important to specify formulation, as available in IR, SR, XL (longest)</td>
</tr>
<tr>
<td>MAOI</td>
<td>phenelzine (Nardil®)</td>
<td>45</td>
<td>60-90</td>
<td>Useful for moderate/severe depression that does not respond to SSRI, atypical depression</td>
</tr>
<tr>
<td></td>
<td>tranylcypromine (Parnate®)</td>
<td>30</td>
<td>10-60</td>
<td>No significant difference when choosing.</td>
</tr>
<tr>
<td>RIMA</td>
<td>moclobemide (Manerix®)</td>
<td>300</td>
<td>300-600</td>
<td>Useful for depression unresponsive to other therapies</td>
</tr>
<tr>
<td>NASSA</td>
<td>mirtazapine (Remeron®)</td>
<td>15</td>
<td>15-45</td>
<td>Useful in depression with prominent features of insomnia, agitation, or cachexia</td>
</tr>
</tbody>
</table>

**Notes**: MAOI = monoamine oxidase inhibitors; NASSA = noradrenergic and specific serotonergic antagonists; NDRI = norepinephrine and dopamine reuptake inhibitors; RIMA = reversible inhibition of MAO-A; SNRI = serotonin and norepinephrine reuptake inhibitors; SSR = selective serotonin reuptake inhibitors; TCA = tricyclic antidepressants
Treatment Approach for Depression

- **optimization**: ensuring adequate drug doses for the individual
- **augmentation**: the addition of a medication that is not considered an antidepressant to an antidepressant regimen (e.g. thyroid hormone, lithium, atypical antipsychotics [specifically: olanzapine, risperidone, aripiprazole])
- **combination**: the addition of another antidepressant to an existing treatment regimen (e.g. the addition of bupropion to an SSRI or SNRI)
- **substitute**: change in the primary antidepressant (within or outside a class)
- **note**: it is important to fully treat the symptoms of depression in order to decrease rates and severity of relapses

### Table 20. Features of Commonly Used Antidepressant Classes

</tbody>
</table>

Serotonin Syndrome
- thought to be due to over-stimulation of the serotonergic system
- can result from medication combinations such as SSRI+MAOI, SSRI+tryptophan, MAOI+meperidine, MAOI+tryptophan
- rare but potentially life-threatening adverse reaction to SSRIs, especially when switching from an SSRI to an MAOI
- symptoms include nausea, diarrhea, palpitations, chills, restlessness, confusion, and lethargy but can progress to myoclonus, hyperthermia, rigor and hypertonicity
- treatment: discontinue medication and administer emergency medical care as needed
- important to distinguish from NMS

Discontinuation Syndrome
- caused by the abrupt cessation of an antidepressant
- observed most frequently with paroxetine, fluvoxamine, and venlafaxine (drugs with shortest half-lives)
- symptoms usually begin within 1-3 d and include: anxiety, insomnia, irritability, mood lability, N/V, dizziness, headache, dystonia, tremor, chills, fatigue, lethargy, and myalgia
- treatment: symptoms may last between 1-3 wk, but can be relieved within 24 h by restarting antidepressant therapy at the same dose the patient was taking and initiating a slow taper over several weeks
- consider using a drug with a longer half-life such as fluoxetine

Mood Stabilizers

General Prescribing Information
- examples: lithium, lamotrigine, divalproex, carbamazepine
- used in conjunction with atypical antipsychotics for managing episodes of bipolar disorder - depression, mania, stabilization
- vary in their ability to "treat" (reduce symptoms acutely) or "stabilize" (prevent relapse and recurrence) manic and depressive symptoms; multi-agent therapy is common
- before initiating, get baseline: CBC, ECG (if patient >45 yr old or cardiovascular risk), urinalysis, BUN, Cr, electrolytes, TSH
- before initiating lithium: screen for pregnancy, thyroid disease, seizure disorder, neurological, renal, cardiovascular diseases
- full effects not for 2-4 wks, thus may need acute coverage with benzodiazepines or antipsychotics

Specific Prescribing Information
- detailed pharmacological guidelines available online from the Canadian Network for Mood and Anxiety Treatments (CANMAT) and International Society for Bipolar Disorders (ISBD)
- for clinical information for treating bipolar disorder (see Mood Disorders, PS9)

</tbody>
</table>
Anxiolytics

- anxiolytics mask or alleviate symptoms; they do not cure them
- **indications**
  - short-term treatment of transient forms of anxiety disorders, insomnia, alcohol withdrawal (especially delirium tremens), barbiturate withdrawal, organic brain syndrome (acute agitation in delirium), EPS and akathisia due to antipsychotics, seizure disorders, musculoskeletal disorders
- **relative contraindications**
  - major depression (except as an adjunct to other treatment), history of drug/alcohol abuse, caution in pregnancy/breastfeeding
- **mechanism of action**
  - benzodiazepines: potentiate binding of GABA to its receptors; results in decreased neuronal activity
  - buspirone: partial agonist of 5-HT1A receptors

Benzodiazepines

- should be used for limited periods (weeks-months) to avoid dependence
- all benzodiazepines are sedating; be wary with use in the elderly
- have similar efficacy, so choice depends on half-life, metabolites and route of administration, OD or bid
- taper slowly over weeks-months because they can cause withdrawal reactions
  - low dose withdrawal: tachycardia, HTN, panic, insomnia, anxiety, impaired memory and concentration, perceptual disturbances
  - high dose withdrawal: hyperpyrexia, seizures, psychosis, death
- avoid alcohol because of potentiation of CNS depression; caution with drinking and driving/machinery use
- **side effects**
  - CNS: drowsiness, cognitive impairment, reduced motor coordination, memory impairment
  - physical dependence, tolerance
- **withdrawal**
  - symptoms: anxiety, insomnia, autonomic hyperactivity (less common)
  - onset: 1-2 d (short-acting), 2-4 d (long-acting)
  - duration: weeks-months
  - complications with above 50 mg diazepam/day: seizures, delirium, arrhythmias, psychosis
  - management: taper with long-acting benzodiazepine
  - similar to but less severe than alcohol withdrawal; can be fatal
- **overdose**
  - commonly used drug in overdose
  - overdose is rarely fatal
  - benzodiazepines are more dangerous and may cause death when combined with alcohol, other CNS depressants or TCAs

Benzodiazepine Antagonist – Flumazenil (Anexate®)

- use for suspected benzodiazepine overdose
- specific antagonist at the benzodiazepine receptor site

Buspirone (Buspar®)

- **primary use**: GAD
- may be preferred over benzodiazepines because are non-sedating, no interaction with alcohol, does not alter seizure threshold, not prone to abuse
- **onset of action**: 2 wk
- **side effects**: dizziness, drowsiness, nausea, headache, nervousness, EPS

### Somatic Therapies

#### Electroconvulsive Therapy

- Various methodological improvements have been made since the first treatment in 1938 to reduce adverse effects
- Modern ECT: induction of a generalized seizure using an electrical pulse through scalp electrodes while the patient is under general anesthesia with a muscle relaxant
- Considerations: unilateral vs. bilateral electrode placement, pulse rate, dose, number and spacing of treatments
- Usual course is 6-12 treatments, 2-3 treatments per wk
- Indications:
  - Depression refractory to adequate pharmacological trial (MDD or Bipolar I depression)
  - High suicide risk
  - Medical risk in addition to depression (dehydration, electrolytes, pregnancy)
  - Previous good response to ECT
  - Familial response to ECT
  - Elderly
  - Psychotic depression
  - Catatonic features
  - Marked vegetative features
  - Acute schizophrenia unresponsive to medication
  - Mania unresponsive to medications
  - OCD refractory to conventional treatment
- Side effects: risk of anesthesia, memory loss (may be retrograde and/or anterograde, tends to resolve by 6-9 mo, permanent impairment controversial), headaches, myalgias
- Unilateral ECT causes less memory loss than bilateral but may not be as effective
- Contraindications: increased intracranial pressure, recent (< 2 wk) MI (not absolute but requires special monitoring)

#### Magnetic Seizure Therapy (MST)

- Early studies demonstrate efficacy for depression as well as anxiety, reduced memory side effects vs. ECT

### ECT in Society

Prior to the 1940's, ECT was performed without the use of muscle relaxants, resulting in seizures with full-scale convulsions and rare but serious complications such as vertebral and long-bone fractures. This practice may have led to negative societal perceptions of ECT, further perpetuated by barbaric depictions in popular culture. Despite ongoing stigmatization, ECT as it is practiced today is an effective and safe option for patients struggling with mental illness.

### Efficacy of ECT in Depression: A Meta-Analytic Review

*J of ECT* 2004; 20:13-20

**Study**: Meta-analysis of randomized and non-randomized control trials.

**Patients**: Individuals with unipolar and bipolar depression.

**Methods**: MEDLINE search for relevant papers from 1966-2003.

**Main Outcomes**: The Hamilton Depression Rating scale was used to determine response to treatment.

**Results**: ECT was found to be superior to simulated ECT, placebo, TCA's, MAOIs, and anti-depressants in general.

**Summary**: ECT is an efficacious treatment modality, particularly in severe and treatment-resistant depression.
Repetitive Transcranial Magnetic Stimulation (rTMS)

- noninvasive production of focal electrical currents in select brain areas using magnetic induction
- **indications**: strong evidence for treatment-resistant depression, pain disorders; possibly efficacious for anxiety disorders, eating disorders, substance use disorders
- **adverse effects**: common - transient local discomfort, hearing issues, cognitive changes; rare - seizure, syncope, mania induction

Neurosurgical Treatments

Ablative/Lesion Procedures

- used for intractable MDD or OCD, efficacy ranges from 25-75% depending on procedure
- **adverse effects**: related to lesion location and size, high risk of suicide in those who are not helped by surgery

Deep Brain Stimulation

- placement of small electrode leads in specific brain areas to alter neuronal signaling, usually for intractable MDD
- response rates (>50% symptom reduction) of 40-70%, adverse effects related to surgical risks and poor treatment response

Vagus Nerve Stimulation

- direct, intermittent electrical stimulation of left cervical vagus nerve via implanted pulse generator
- used for chronic, recurrent MDD that has failed previous therapy and ECT; slow onset, approximately 30% response rate at 1 yr

Other Therapy Modalities

Phototherapy (Light Box Therapy)

- bright light source exposure, best in morning, for 30-60 minutes (usually 10,000 lux)
- proposed mechanisms: reverses pathological alterations in circadian rhythm through action on suprachiasmatic nucleus
- **indications**: SAD, non-seasonal depression (as augmentation), sleep disorders
- **adverse effects**: mania induction, reaction with photosensitizing drug or photosensitive eye or skin conditions

Aerobic Exercise

- moderate-intense aerobic exercise is associated with acute increased secretion of serotonin, phenethylamine, BDNF, endogenous opioids and cannabinoids (likely this combination is what contributes to the “runner’s high”)
- long term increases gray matter in multiple areas, as well as improvements in cognition, memory and stress tolerance
- **indications**: ongoing research suggests efficacy as adjunctive treatment for MDD; may be helpful in PTSD, schizophrenia
## Canadian Legal Issues

### Common Forms

**Table 23. Common Forms Under the Mental Health Act (in Ontario)**

<table>
<thead>
<tr>
<th>Form</th>
<th>Who Signs</th>
<th>When</th>
<th>Expiration Date</th>
<th>Right of Patient to Review Board Hearing</th>
<th>Options Before Form Expires</th>
</tr>
</thead>
<tbody>
<tr>
<td>Form 1: Application by physician to hospitalize a patient for psychiatric assessment against his/her will to a schedule 1 facility (Form 42 given to patient)</td>
<td>Any MD</td>
<td>Within 7 d after examination of the patient</td>
<td>72 h after hospitalization Void if not implemented within 7 d</td>
<td>No</td>
<td>Form 3 + 30 or voluntary admission or Send home ± follow-up</td>
</tr>
<tr>
<td>Form 2: Order for a psychiatric assessment against his/her will which is ordered by Justice of the Peace</td>
<td>Justice of the Peace</td>
<td>No statutory time restriction</td>
<td>7 d from when completed Purpose of form is complete once patient brought to hospital</td>
<td>No</td>
<td>Form 1 + 42 or Send home ± follow-up</td>
</tr>
<tr>
<td>Form 3: Certificate of involuntary admission to a schedule 1 facility (Form 30 given to patient, notice to rights advisor)</td>
<td>Attending MD (different than MD who completed Form 1)</td>
<td>Before expiration of Form 1</td>
<td>14 d</td>
<td>Yes</td>
<td>Form 4 + 30 or Voluntary admission (Form 5)</td>
</tr>
<tr>
<td>Form 4: Certificate of renewal of involuntary admission to a schedule 1 facility (original Form 30 given to patient, notice to rights advisor)</td>
<td>Attending MD following patient on Form 3</td>
<td>Prior to expiration of Form 3</td>
<td>First: 1 mo Second: 2 mo Third: 3 mo (max)</td>
<td>Yes</td>
<td>Form 4 + 30 or Voluntary admission (Form 5)</td>
</tr>
<tr>
<td>Form 5: Change to informal/voluntary status</td>
<td>Attending MD following patient on Form 3/4</td>
<td>Whenever deemed appropriate</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Form 30: Notice to patient that they are now under involuntary admission on either Form 3 or 4. Original to the patient, copy to chart</td>
<td>Attending MD</td>
<td>Whenever Form 3 or Form 4 filled</td>
<td>N/A</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td>Form 33: Notice to patient that patient is incapable of consenting to treatment of mental disorder, and/or management of property and/or disclosure of health information (original copy to patient)</td>

### Consent

- see *Ethical, Legal, and Organizational Medicine, ELOAM7*
Community Treatment Order (CTO)

- purpose: a CTO orders a person suffering from a serious mental disorder to receive treatment and supervision in the community. Based on a comprehensive plan outlining medications, appointments, and other care believed necessary to allow the person to live in the community (vs. in a psychiatric facility, where things are more restrictive)
- intended for those who
  - due to their serious mental disorder, experience a pattern of admission to a psychiatric facility where condition is usually stabilized
  - after being released, these patients often lack supervision and stop treatment, leading to destabilization
  - due to the destabilization of their condition, these patients usually require re-admission to hospital
  - if CTO violated (e.g. treatment not taken), patient brought in by police to hospital for treatment as per CTO
- criteria for a physician to issue a CTO
  - patient with a prior history of hospitalization
  - a community treatment plan for the person has been made
  - examination by a physician within the previous 72 h before entering into the CTO plan
  - ability of the person subject to the CTO to comply with it
  - consultation with a rights advisor and consent of the person or the person’s substitute decision maker
- CTOs are valid for 6 mo unless they are renewed or terminated at an earlier date such as:
  - where the person fails to comply with the CTO
  - when the person or his/her substitute decision-maker withdraws consent to the community treatment plan
- CTO process is consent-based and all statutory protections governing informed consent apply
- the rights of a person subject to a CTO include
  - the right to a review by the Consent and Capacity Board with appeal to the courts each time a CTO is issued or renewed
  - a mandatory review by the Consent and Capacity Board every second time a CTO is renewed
  - the right to request a re-examination by the issuing physician to determine if the CTO is still necessary for the person to live in the community
  - the right to review findings of incapacity to consent to treatment
  - provisions for rights advice

- CVP: coal worker’s pneumoconiosis
- DC: disseminated intravascular coagulation
- DLCO: carbon monoxide diffusing capacity of lung
- EBUS: endobronchial ultrasound
- ECMO: extracorporeal membrane oxygenation
- ERV: expiratory reserve volume
- ETT: endotracheal tube
- FEV1: forced expiratory volume in 1 second
- FEF: forced expiratory flow rate
- FiO2: fraction of oxygen in inspired air
- FRC: functional residual capacity
- FO2: fraction of oxygen in inspired air
- FIO2: fraction of inspired oxygen
- GLM: glomerular basement membrane
- H/A: headache
- H: hypothyroidism
- HLA: hypothyroidism
- HRT: hormone replacement therapy
- IBD: inflammatory bowel disease
- IC: insulin-dependent diabetes mellitus
- IC: insulin-dependent diabetes mellitus
- ICS: inhaled corticosteroid
- ICP: intracranial pressure
- IC: inspiratory capacity
- IPF: idiopathic pulmonary fibrosis
- IPP: idiopathic pulmonary fibrosis
- IC: inspiratory capacity
- LVEDD: left ventricular end diastolic diameter
- LVEDP: left ventricular end diastolic pressure
- LV: left ventricle
- LV: left ventricular failure
- MAC: Mycobacterium avium complex
- MDR: metronidazole
- MEP: maximum expiratory pressure
- MIP: minimum inspiratory pressure
- NSAID: nonsteroidal anti-inflammatory drug
- NSC: normal saline
- NPPV: non-invasive positive pressure ventilation
- PA: pulmonary arterial pressure
- Pao2: arterial partial pressure of oxygen
- PaCO2: arterial partial pressure of carbon dioxide
- PaCO2: arterial partial pressure of carbon dioxide
- Pao2: arterial partial pressure of oxygen
- PCWP: pulmonary capillary wedge pressure
- PE: pulmonary embolism
- PEEP: positive end expiratory pressure
- PET: pulmonary embolism
- PFT: pulmonary function tests
- PMNs: polymorphonuclear cells
- PP: pulse pressure
- PSV: positive pressure ventilation
- PTH: parathyroid hormone
- PTT: partial thromboplastin time
- PV: pulmonary venous pressure
- RAV: right atrial volume
- RAP: right atrial pressure
- RBBB: right bundle branch block
- RF: rheumatoid factor
- RV: residual volume
- RVEDV: right ventricular end diastolic volume
- RVSP: right ventricular systolic pressure
- RVH: right ventricular hypertension
- SC: squamous cell carcinoma
- SCL: small cell lung cancer
- SV: stroke volume
- SVC: superior vena cava
- SVR: systemic vascular resistance
- TCA: tricyclic antidepressant
- TLF: total lung capacity
- TAC: total arterial compliance
- TC: total parenteral nutrition
- UC: ulcerative colitis
- UN: upper urinary tract infection
- VD: ventilation-perfusion
- VATS: video-assisted thoracoscopic surgery
- VCP: ventilatory capacity
- VCSS: ventilatory capacity
- VTE: venous thromboembolism
- V wave: venous return
- V1: tidal volume

## Differential Diagnoses of Common Presentations

### Table 1. Differential Diagnosis of Dyspnea

**Acute Dyspnea (minutes-hours)**
- **Cardiac causes**
  - Ischemic heart disease
  - CHF exacerbation
  - Cardiac tamponade
- **Pulmonary causes**
  - Upper airway obstruction (anaphylaxis, foreign body)
  - Airway disease (asthma, COPD exacerbation, bronchitis)
  - Parenchymal lung disease (ARDS, pneumonia)
  - Pulmonary vascular disease (PE, vasculitis)
  - Pleural disease (pneumothorax, tension pneumothorax)
  - Respiratory control (metabolic acidosis, ASA toxicity)

**Psychiatric causes**
- Anxiety/psychosomatic

### Table 2. Differential Diagnosis of Chest Pain

**Nonpleuritic**
- **Pulmonary**
  - Pneumonia
  - PE
  - Neoplasm
- **Cardiac**
  - MI
  - Myocarditis/pericarditis
- **Esophageal**
  - GERD
  - Spasm
  - Esophagitis
  - Ulceration
  - Achalasia
  - Neoplasm
  - Esophageal rupture

**Mediastinal**
- Lymphoma
- Thymoma

**Subdiaphragmatic**
- PUD
- Gastritis
- Biliary colic
- Pancreatitis

**Vascular**
- Dissecting aortic aneurysm

**MSK**

- Skin
- Breast
- Ribs

**Pleuritic**
- **Pulmonary**
  - Pneumonia
  - PE
  - Neoplasm
- **Cardiac**
  - Heart failure
  - Mitral valve disease
  - Pneumothorax
  - Empyema
- **GI**
  - Subphrenic abscess
  - Pancreatitis

### Table 3. Differential Diagnosis of Hemoptysis

- **Airway Disease**
  - Acute or chronic bronchitis
  - Bronchiectasis
  - Bronchogenic CA
  - Bronchial carcinoid tumour

- **Parenchymal Disease**
  - Pneumonia
  - TB
  - Lung abscess

- **Vascular Disease**
  - PE
  - Elevated pulmonary venous pressure:
  - LVF
  - Mitral stenosis
  - Vascular malformation
  - Vasculitis
  - Goodpasture’s syndrome
  - Idiopathic pulmonary hemosiderosis

- **Miscellaneous**
  - Impaired coagulation
  - Pulmonary endometriosis

### Table 4. Differential Diagnosis of Cough

- **Airway Irritants**
  - Inhaled smoke, dusts, fumes
  - Postnasal drip (upper airway cough syndrome)
  - Aspiration
  - Gastric contents (GERD)
  - Oral secretions
  - Foreign body

- **Airway Disease**
  - URTI including postnasal drip and sinusitis
  - Acute or chronic bronchitis
  - Bronchiectasis
  - Neoplasm
  - External compression by node or mass lesion
  - Asthma
  - COPD

- **Parenchymal Disease**
  - Pneumonia
  - Lung abscess
  - Interstitial lung disease
  - CHF
  - Drug-induced (e.g., ACEI)

Pulmonary Function Tests

• useful in differentiating the pattern of lung disease (obstructive vs. restrictive)
• assess lung volumes, flow rates, and diffusion capacity (Figures 5A and 5B)
• note: normal values for FEV$_1$ are approximately ±20% of the predicted values (for age, sex, and height); ethnicity may affect predicted values

| Table 5. Comparison of Lung Flow and Volume Parameters in Obstructive vs. Restrictive Lung Disease |
|-----------------------------------|-----------------------------------|
| **Obstructive**                   | **Restrictive**                   |
| Decreased flow rates (most marked during expiration) | Decreased lung compliance |
| Air trapping (increased RV/TLC)   | Decreased lung volumes           |
| Hyperinflation (increased FRC, TLC) |                                |

Arterial Blood Gases
- provides information on acid-base and oxygenation status
- see Nephrology, NP14

Approach to Acid-Base Status
1. Is the pH acidemic (pH <7.35), alkalemic (pH >7.45), or normal (pH 7.35-7.45)?
2. What is the primary disturbance?
   - metabolic: change in HCO₃⁻ and pH in same direction
   - respiratory: change in HCO₃⁻ and pH in opposite directions
3. Is there appropriate compensation? (see Table 8)
   - metabolic compensation occurs over 2-3 d reflecting altered renal HCO₃⁻ production and excretion
   - respiratory compensation through ventilatory control of P₇,CO₂ occurs immediately
   - inadequate compensation may indicate a second acid-base disorder

</tbody>
</table>

4. If there is metabolic acidosis, what is the anion gap and osmolar gap?
   - anion gap = |Na⁺| – (|Cl⁻| + |HCO₃⁻|); normal ≤ 10-15 mmol/L
   - osmolar gap = measured osmolarity – calculated osmolarity = measured – (2|Na⁺| + glucose + urea); normal ≤ 10 mmol/L

5. If anion gap is increased, is the change in bicarbonate the same as the change in anion gap?
   - if not, consider a mixed metabolic picture

| **Mechanical Hyperventilation (Excessive Mechanical Ventilation)** |

- see Nephrology: NP15 for differential diagnosis of metabolic acidosis and alkalosis

---

**ABG Normal Values**
- pH 7.35-7.45
- HCO₃⁻ 22-26 mEq/L
- PaCO₂ 35-45 mm Hg
- PaO₂ 80-100 mm Hg

Acidosis ↔ Hyperkalemia
Alkalosis ↔ Hypokalemia

Note: Mixed acid-base disturbances can still have a "normal" pH

Osmolar Gap = measured osmolarity – calculated osmolarity; for calculated osmolarity think "2 salts and a sticky BUN" (2Na + glucose + urea)

**Anion Gap Metabolic Acidosis**
- MUDPILES CAT
  - Methanol
  - Uremia
  - Diabetic ketoacidosis/starvation
  - Ketaacidosis
  - Phenformin/Paraldehyde
  - Isoniazid, Iron, Ibuprofen
  - Lactate
  - Ethylene glycol
  - Salicylates
  - Cyanide, Carbon dioxide
  - Alcoholic ketoacidosis
  - Toluene, Theophylline
**Diseases of Airway Obstruction**

### Pneumonia
- see [Infectious Diseases], ID7

### Asthma
- see [Family Medicine], FM16 and [Pediatrics], P89

**Definition**
- chronic inflammatory disorder of the airways resulting in episodes of reversible bronchospasm causing airflow obstruction
- associated with reversible airflow limitation and airway hyper-responsiveness to endogenous or exogenous stimuli

**Epidemiology**
- common, 7-10% of adults, 10-15% of children
- most children with asthma significantly improve in adolescence
- often family history of atopy (asthma, allergic rhinitis, eczema)
- occupational asthma (organic allergies, isocyanates, animals, etc.)
Pathophysiology
- airway obstruction \( \rightarrow \) V/Q mismatch \( \rightarrow \) hypoxemia \( \rightarrow \) ↑ ventilation \( \rightarrow \) ↓ \( P_{CO2} \) \( \rightarrow \) ↑ pH and muscle fatigue \( \rightarrow \) ↓ ventilation, ↑ \( P_{CO2} \)/↓ pH

Signs and Symptoms
- dyspnea, wheezing, chest tightness, cough (especially nocturnal), sputum
- symptoms can be paroxysmal or persistent
- signs of respiratory distress (see Figure 4)
- pulsus paradoxus

Table 11. Criteria for Determining if Asthma is Well Controlled

| Criteria                                                                 | Well Controlled

</table>

Adapted from: Can Respir J 2012; 19:127-184

Investigations
- \( O_2 \) saturation
- ABCs (consist in acute exacerbation, along with peak flows, in Emergency Department)
  - decreased \( P_{O2} \) during attack (V/Q mismatch)
  - decreased \( P_{CO2} \) in mild asthma (hyperventilation)
  - normal or increased \( P_{CO2} \) is an ominous sign: patient is no longer able to hyperventilate (worsened airway obstruction or respiratory muscle fatigue)
- PFTs (do when stable)

Adapted from: Can Respir J 2012; 19:127-184

Treatment
- environment: avoid triggers
- patient education: features of the disease, goals of treatment, self-monitoring
- pharmacological
  - symptomatic relief in acute episodes: short-acting \( \beta_2 \)-agonist, anticholinergic bronchodilators, oral steroids, addition of a long acting \( \beta_2 \)-agonist
  - long-term prevention: inhaled/oral corticosteroids, anti-allergic agents, long-acting \( \beta_2 \)-agonists, methylxanthine, LTRA, anti-IgE antibodies (e.g. Xolair®)

Emergency Management of Asthma (see Emergency Medicine, ER29)
1. inhaled \( \beta_2 \)-agonist first line (MDI route and spacer device recommended)
2. systemic steroids (PO or IV if severe)
3. if severe add anticholinergic therapy ± magnesium sulphate
4. rapid sequence intubation in life-threatening cases (plus 100% \( O_2 \) monitors, IV access)
5. SC/IV adrenaline if caused by anaphylaxis, IV salbutamol if unresponsive
6. corticosteroid therapy at discharge

Asthma Triggers
- URTIs
- Allergens (pet dander, house dust, molds, cockroach)
- Irritants (cigarette smoke, air pollution)
- Drugs (NSAIDs, \( \beta \)-blockers)
- Preservatives (sulphites, MSG)
- Other (emotion/anxiety, cold air, exercise, GERD)

Signs of Poor Asthma Control
DANGERS
Daytime Sx >4 times/wk
Activities reduced
Nighttime Sx >1 time/wk
GP visits
ER visits
Rescue puffer (SABA) use >4 times/wk
School and work absences

Consider LABA for night-time symptoms

LTRA in Addition to Usual Care for Acute Asthma in Adults and Children
Cochrane DB Syst Rev 2012;CD006100
Purpose: To determine if the addition of LTRA is beneficial to patients with acute asthma receiving inhaled bronchodilators and systemic corticosteroids.
Methods: RCTs in Cochrane Airways Group’s Specialised Register of trials that compared LTRA and standard vs. placebo and standard in people with acute asthma of any age.
Results: 8 trials, 1,470 adults and 470 children. For oral treatment, no significant difference between LTRAs and control in hospital admission (RR 0.86; 95% CI 0.75-0.98) or requirement for additional care (RR 0.87; 95% CI 0.61-1.26). LTRAs improved FEV1 in adults (mean difference 0.08, 95% CI 0.01-0.14) but not in children. No significant difference in adverse events between LTRAs and control (RR 0.81; 95% CI 0.23-2.90). Similar results were found for intravenous treatment.
Conclusions: Currently, there is no evidence to support routine use of LTRAs in acute asthma.

Natural Progression of COPD
40s
- Chronic productive cough, wheezing occasionally
50s
- 1st acute chest illness
60s
- Dyspnea on exertion, increasing sputum, more frequent exacerbations

Late
- Hypoxemia with cyanosis,
- Stage polythemia, hypercapnia (morning headache), cor pulmonale, weight loss

GOLD Classification of the Severity of COPD
GOLD 1 Mild FEV1 >80% of predicted
GOLD 2 Moderate 50% ≤ FEV1 <80% of predicted
GOLD 3 Severe 30% ≤ FEV1 <50% of predicted
GOLD 4 Very Severe FEV1 <30% of predicted

Environmental Control, Education, and Written Action Plan

Confirm Diagnosis

Chronic Obstructive Pulmonary Disease

- Definition
  - Progressive and irreversible condition of the lung characterized by chronic obstruction to airflow with many patients having periodic exacerbations, gas trapping, lung hyperinflation, and weight loss
  - 2 subtypes: chronic bronchitis and emphysema (usually coexist to variable degrees)
  - Gradual decrease in FEV1 over time with episodes of acute exacerbations

Table 13. Clinical and Pathologic Features of COPD*

<table>
<thead>
<tr>
<th>Chronic Bronchitis</th>

<td></td>
</tr>
<tr>
<td>Accounts for about 1% of emphysema cases</td>
<td></td>
</tr>
<tr>
<td>α1-antitrypsin deficiency, primarily affects lower lobes</td>
<td></td>
</tr>
</tbody>
</table>

Note: Table 13 includes Clinical and Pathologic Features of COPD.*

Risk Factors

- Smoking is #1 risk factor

- Others
  - Environmental: air pollution, occupational exposure, exposure to wood smoke or other biomass fuel for cooking
  - Treatable factors: α1-antitrypsin deficiency, bronchial hyperactivity
  - Demographic factors: age, family history, male sex, history of childhood respiratory infections, low socioeconomic status

Pulmonary Embolism in Patients with Unexplained Exacerbation of COPD: Prevalence and Risk Factors

- Study: Prospective cohort study of 211 patients with COPD (all current and former smokers) admitted to hospital for severe COPD exacerbation of unknown origin
- Measurements: All patients received spiral CT angiogram (CTA) and various compression ultrasonography of both legs
- Results: 25% of patients met diagnostic criteria for PE (± CTA or ± US)
- Conclusions: Prevalence of PE in patients hospitalized for COPD exacerbation of unknown origin is 25%. Therefore, all patients presenting to hospital with COPD exacerbation without obvious cause require PE workup (leg dopplers or CTA – decision of which to use depends on pre-test probability of the patient)

Non-Invasive Positive Pressure Ventilation for Treatment of Respiratory Failure due to Exacerbations of COPD

- Study: Cochrane Systematic Review, 14 RCTs
- Population: 758 adult patients with COPD and acute respiratory failure due to COPD exacerbation
- Intervention: Usual medical care (UMC) and Non-invasive positive ventilation (NPPV) vs. UMC alone
- Primary Outcome: Treatment failure, mortality, and tracheal intubation
- Results: The risks for all primary outcomes were reduced with NPPV use: treatment failure (RR 0.49); mortality (RR 0.52); and intubation use (RR 0.81). Length of hospital stay was a significant mean 3.4 days shorter, but no difference between ICU length of stay. There is a small and significant improvement in pH (weight mean difference (WMD)=0.04), PCO2 (WMD=-0.40 mm Hg), and respiratory rate (WMD=-3.08 bpm) within 1 h post-treatment with NPPV. Complications associated with treatment were reduced in the NPPV treatment arm (RR 0.30)
- Conclusion: For patients in respiratory failure due to a COPD exacerbation, NPPV is effective in reducing treatment failure, mortality, and need for intubation when used as a first line treatment adjunct to UMC.

</tr>
</tbody>
</table>

**SYMPTOMATIC RELIEF (no mortality benefit)**

**Bronchodilators (mainstay of current drug therapy, used in combination)**

- Short-acting anticholinergics (e.g. ipratropium bromide) and short-acting β2-agonists (e.g. salbutamol, terbutaline)
  - LABAs (e.g. salmeterol, formoterol, indacaterol) and long-acting anticholinergics (e.g. tiotropium bromide, glycopyrronium bromide)
  - More sustained effects for moderate to severe COPD

**Inhaled corticosteroid (ICS) + LABA combination (e.g. Advair®: fluticasone + salmeterol, Symbicort®: budesonide + formoterol)**

| Theophylline: weak bronchodilator; limited evidence to suggest combination with bronchodilator |
| Side effects: nervous tremor, nausea/vomiting/diarrhea, tachycardia, arrhythmias, sleep changes |
| PDE4 inhibitor: roflumilast (Daxxas®) anti-inflammatory medication useful in COPD with chronic bronchitis, severe airflow obstruction, frequent exacerbations |

**Corticosteroids**

ICS therapy is contraindicated and ICS should only be used with a LABA in combination in patients with a history of exacerbations

COPD airways are usually inflamed but often not responsive to steroids, therefore avoid chronic systemic glucocorticoids (although oral steroids are very important when treating exacerbations)

**Surgical**

Lung volume reduction surgery (resection of emphysematous parts of lung, associated with higher mortality if FEV1 < 20%, lung transplant

**Other**

Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance

*Note that the distinction between “blue bloaters” and “pink puffers” is more of historical than practical interest as most COPD patients have elements of both.

Table 15. Treatment of Stable COPD

**PROLONG SURVIVAL**

**Outcome:** Exacerbation rates, hospitalizations, mortality, lung function and adverse effects.

**Results:** In patients with COPD, inactive vaccine correlated with fewer exacerbations per vaccinated subject than placebo (weighted mean difference (WMD) -0.37, 95% CI -0.64 to -0.11). Inactivated vaccine resulted in fewer influenza-related infections than placebo (WMD 0.19, 95% CI 0.07-0.46). There was also an increased risk of local mild, transient adverse reactions with the vaccine.

**Conclusion:** There appears to be a reduction in influenza-related infections, as well as exacerbations in patients with COPD receiving the vaccine.

---

Remember to step down therapy to lowest doses which control symptoms/signs of bronchoconstriction

**Influenza Vaccine for Patients with Chronic Obstructive Pulmonary Disease**

**Study:** Cochrane Systematic Review, 11 RCTs included, 6 specifically in COPD patients.

**Population:** Six of the studies were done on COPD patients in particular, while the others were on elderly and high-risk individuals. Asthma patients were excluded.

**Intervention:** Live or inactivated virus vaccines vs. placebo.

**Outcome:** Exacerbation rates, hospitalizations, mortality, lung function and adverse effects.

**Results:** In patients with COPD, inactive vaccine correlated with fewer exacerbations per vaccinated subject than placebo (weighted mean difference (WMD) -0.37, 95% CI -0.64 to -0.11). Inactivated vaccine resulted in fewer influenza-related infections than placebo (WMD 0.19, 95% CI 0.07-0.46). There was also an increased risk of local mild, transient adverse reactions with the vaccine.

**Conclusion:** There appears to be a reduction in influenza-related infections, as well as exacerbations in patients with COPD receiving the vaccine.

**Different Durations of Corticosteroid Therapy for Exacerbations of Chronic Obstructive Pulmonary Disease**

**Study:** Cochrane systematic review, 8 studies, 326 patients, with severe or very severe COPD.

**Population:** 65% of included studies were in COPD patients.

**Intervention:** Long-term systemic corticosteroid treatment (n = 657; odds ratio (OR) 0.72, 95% confidence interval (CI) 0.46 to 1.14), which was equivalent to 22 fewer per 1000 for short-duration treatment (95% CI 19 fewer to 34 more). No difference in risk of relapse (a new event) was observed between short-duration and longer-duration systemic corticosteroid treatment (n = 493; OR 1.04, 95% CI 0.70 to 1.59), which was equivalent to nine fewer per 1000 for short-duration treatment (95% CI 68 fewer to 100 more). Time to the next COPD exacerbation did not differ in one large study that was powered to detect non-inferiority and compared five days versus 14 of systemic corticosteroid treatment (n = 311; hazard ratio 0.98, 95% CI 0.86 to 1.12). In five studies no difference in the likelihood of an adverse event was found between short-duration and longer-duration systemic corticosteroid treatment (n = 502; OR 0.89, 95% CI 0.46 to 1.79, or nine fewer per 1000 [95% CI 44 fewer to 51 more]). Length of hospital stay (n = 421; mean difference (MD) -0.61 days, 95% CI -1.51 to 0.28) and lung function at the end of treatment (n = 185; MD FEV1 -0.04 L; 95% CI -0.19 to 0.01) did not differ between short-duration and longer-duration treatment.

**Conclusion:** 5 d of oral corticosteroids is likely to be sufficient for treatment of adults with acute exacerbations of COPD, and this review suggests that the likelihood is low that shorter courses of systemic corticosteroids (of around five days) lead to worse outcomes than are seen with longer (10 to 14 d) courses.
Acute Exacerbations of COPD

- Definition:
  - Sustained (>24-48 h) worsening of dyspnea, cough, or sputum production leading to an increased use of medications

- Etiology:
  - Viral URTI, bacteria, air pollution, CHF, PE, MI must be considered

- Management:
  - ABCs, consider assisted ventilation if decreasing LOC or poor ABGs
  - O₂: target 88-92% SaO₂ for CO₂ retainers
  - Bronchodilators by MDI with spacer or nebulizer
  - SABA + anticholinergic, e.g. salbutamol and ipratropium bromide via nebulizers x 3 back-to-back q15min
  - Systemic corticosteroids: IV dexamethasone or oral prednisone
  - Antibiotics for exacerbations with increased sputum production and at least one of the following: increased dyspnea or sputum purulence
  - Simple exacerbation (no risk factors): amoxicillin, 2nd or 3rd generation cephalosporin, macrolide, or TMP-SMX
  - Complicated exacerbation (one of: FEV₁ ≤50% predicted, ≥4 exacerbations per year, ischemic heart disease, home O₂ use, chronic oral steroid use): fluoroquinolone or β-lactam + β-lactamase inhibitor (amoxicillin/clavulanate)
  - Post exacerbation: rehabilitation with general conditioning to improve exercise tolerance

- ICU Admission
  - For life threatening exacerbations
  - Ventilatory support
  - Non-invasive: NPPV, BiPAP
  - Conventional mechanical ventilation

Prognosis in COPD

- Prognostic factors
  - Level of dyspnea is the single best predictor
  - Development of complications, e.g. hypoxemia or cor pulmonale
  - 5 yr survival
    - FEV₁ <1 L = 50%
    - FEV₁ <0.75 L = 33%
  - BODE index for risk of death in COPD
    - Greater score = higher probability the patient will die from COPD; score can also be used to predict hospitalization
  - 10 point index consisting of four factors
    - Body mass index (BMI): <21 (+1 point)
    - Obstruction (FEV₁): 50-64% (+1), 36-49% (+2), <35% (+3)
    - Dyspnea (MRC scale): walks slower than people of same age on level surface, stops occasionally (+1), stops at 100 yards or a few minutes on the level (+2), too breathless to leave house or breathless when dressing/undressing (+3)
    - Exercise capacity (6 minute walk distance): 250-349 m (+1), 150-249 m (+2), <149 m (+3)

Surgery

Systemic Corticosteroids for Acute Exacerbations of Chronic Obstructive Pulmonary Disease

**Diagnosis:**

- Acute exacerbations of COPD (AECOPD)

**Intervention:**

- Oral or parenteral corticosteroids vs. placebo

**Outcome:**

- Treatment failure, risk of relapse, time to next COPD exacerbation, likelihood of adverse event, length of hospital stay, and lung function at end of treatment

**Results:**

- Systemic corticosteroids reduced the risk of treatment failure by over half compared with placebo in nine studies (n = 917) with median treatment duration 14 d, odds ratio (OR) 0.49 (95% CI 0.35-0.67). The evidence was graded as high quality and it would have been necessary to treat nine people (95% CI 7.1-14) with systemic corticosteroids to avoid one treatment failure. There was moderate-quality evidence for a lower rate of relapse by one month for treatment with systemic corticosteroid in two studies (n = 415) (hazard ratio [HR] 0.78; 95% CI 0.63-0.97). Mortality up to 30 d was not reduced by treatment with systemic corticosteroids compared with control in 12 studies (n = 1,319; OR 1.00; 95% CI 0.60-1.66). FEV₁ measured up to 72 h, showed significant treatment benefits (1 studies; n = 849; mean difference [MD] 140 mL, 95% CI 100-180); however, this benefit was not observed at later time points. The likelihood of adverse events increased with corticosteroid treatment (OR 2.33; 95% CI 1.99-3.64). The risk of hyperglycemia was significantly increased (OR 2.97; 95% CI 1.66-4.19). For general hospital treatment, duration of hospitalization was significantly shorter with corticosteroid treatment (MD -1.22 d; 95% CI -2.26 to -0.18), with no significant difference in the duration of inpatient treatment, duration of hospitalization was significantly shorter with corticosteroid treatment (MD -1.22 d; 95% CI -2.26 to -0.18), with no difference in length of stay in the intensive care unit (ICU) setting. Comparison of parenteral versus oral treatment showed no significant difference in the primary outcomes of treatment failure, relapse or mortality or for any secondary outcomes.

**Conclusion:**

- There is high-quality evidence to support treatment of exacerbations of COPD with systemic corticosteroids by the oral or parenteral route in reducing the likelihood of treatment failure and relapse by 1 mo. Shortening length of stay in hospital inpatients not requiring assisted ventilation in ICU and giving earlier improvement in lung function and symptoms. There is no evidence of benefit for parenteral treatment compared with oral treatment with corticosteroid on treatment failure, relapse or mortality. There is an increase in adverse drug effects with corticosteroid treatment, which is greater with parenteral administration compared with oral treatment.
## Bronchiectasis

### Definition
- irreversible dilatation of airways due to inflammatory destruction of airway walls resulting from persistently infected mucus
- usually affects medium sized airways
- *P. aeruginosa* is the most common pathogen; *S. aureus, H. influenzae*, and nontuberculous mycobacteria also common

### Table 16. Etiology and Pathophysiology of Bronchiectasis

<table>
<thead>
<tr>
<th>Obstruction</th>
<th>Post-Infectious (results in dilatation of bronchial walls)</th>
<th>Impaired Defenses (leads to interference of drainage, chronic infections, and inflammation)</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td></td>
<td>MAC</td>
<td></td>
</tr>
</tbody>
</table>

### Signs and Symptoms
- chronic cough, purulent sputum (but 10-20% have dry cough), hemoptysis (can be massive), recurrent pneumonia, local crackles (inspiratory and expiratory), wheezes
- clubbing
- may be difficult to differentiate from chronic bronchitis

### Investigations
- PFTs: often demonstrate obstructive pattern but may be normal
- CXR
  - nonspecific: increased markings, linear atelectasis, loss of volume in affected areas
  - specific: “tram tracking” – parallel narrow lines radiating from hilum, cystic spaces, honeycomb like structures
- high-resolution thoracic CT (diagnostic, gold standard)
  - 87-97% sensitivity, 93-100% specificity
  - “signet ring”: dilated bronchi with thickened walls where diameter bronchus > diameter of accompanying artery
- sputum cultures (routine + AFB)
- serum Ig levels
- sweat chloride if cystic fibrosis suspected (upper zone predominant)

### Treatment
- vaccination: influenza and Pneumovax®
- antibiotics (oral, IV, inhaled): routinely used for mild exacerbations, driven by sputum sensitivity; macrolides may be used chronically for an anti-inflammatory effect
- inhaled antibiotics (tobramycin) used chronically to suppress pseudomonas and reduce exacerbations
- inhaled corticosteroids: decrease inflammation and improve FEV₁
- oral corticosteroids for acute, major exacerbations
- chest physiotherapy, breathing exercises, physical exercise
- pulmonary resection: in selected cases with focal bronchiectasis

## Cystic Fibrosis

- see *Pediatrics*, P90

### Pathophysiology
- chloride transport dysfunction: thick secretions from exocrine glands (lung, pancreas, skin, reproductive organs) and blockage of secretory ducts

### Clinical Features
- results in severe lung disease, pancreatic insufficiency, diabetes, and azoospermia
- other manifestations: meconium ileus in infancy, distal ileal obstruction in adults, sinusitis, liver disease
- chronic lung infections
  - *S. aureus*: early
  - *P. aeruginosa*: most common
  - *B. cepacia*: worse prognosis but less common
  - *Aspergillus fumigatus*

### Investigations
- sweat chloride test
  - increased concentrations of NaCl and K⁺ ([Cl⁻] >60 mmol/L is diagnostic in children)
- heterozygotes have normal sweat tests (and no symptoms)
• PFTs
  - early: airflow limitation in small airways
  - late: severe airflow obstruction, hyperinflation, gas trapping, decreased DL_{CO} (very late)
• ABGs
  - hypoxemia, hypercapnia later in disease with eventual respiratory failure and cor pulmonale
• CXR
  - hyperinflation, increased pulmonary markings (especially upper lobes)

Treatment
- chest physiotherapy and postural drainage
- bronchodilators (salbutamol ± ipratropium bromide)
- inhaled mucolytic (reduces mucus viscosity), hypertonic saline DNase
- inhaled tobramycin
- lung transplant
- pancreatic enzyme replacements

Prognosis
- depends on: infections (cepacia colonization), FEV₁, acute pulmonary exacerbations, lung transplant vs. non-lung transplant

Interstitial Lung Disease

Definition
- a group of disorders which cause progressive scarring of lung tissue
- this scarring can eventually impair lung function and gas exchange

Pathophysiology
- inflammatory and/or fibrosing process in the alveolar walls → distortion and destruction of normal alveoli and microvasculature
- typically associated with
  - lung restriction (decrease in TLC and VC)
  - decreased lung compliance (increased or normal FEV₁/FVC)
  - impaired diffusion (decreased DL_{CO})
  - hypoxemia due to V/Q mismatch (usually without hypercapnia until end stage)
  - pulmonary HTN and cor pulmonale occur with advanced disease secondary to hypoxemia and blood vessel destruction

Etiology
- >100 known disorders can cause ILD
- majority due to unknown agents or cause

Table 17. Interstitial Lung Diseases

- Antibiotics (nitrofurantoin)
- Anti-inflammatory agents (methotrexate)
- Cardiovascular drugs (amiodarone)
- Antineoplastic agents (chemotherapy agents)
- Illicit drugs
- Radiation

ILD Associated with Pulmonary Vasculitis
- Granulomatosis with Polyangiitis (GPA)
- Goodpasture’s syndrome
- Idiopathic pulmonary hemosiderosis

Inherited Disorders
- Familial IPF
- Telomerase mutations
- Neurofibromatosis
- Tuberculosis
- Gaucher’s disease

Alveolar Filling Disorders
- Chronic eosinophilic pneumonia
- Pulmonary alveolar proteinosis

FASSTEN: Farmer’s lung, ankylosing spondylitis, silicosis, tuberculosis, eosinophilic granuloma, lymphangioleiomyomatosis
BADRASH: Bronchiolitis obliterans with organizing pneumonia, asbestosis, drugs (nitrofurantoin, hydralazine, INH, amiodarone, many chemo drugs), rheumatologic disease, aspiration, scleroderma, Hamman Rich (acute interstitial pneumonia) and IPF
Signs and Symptoms

- dyspnea, especially on exertion
- nonproductive cough
- crackles (dry, fine, end-inspiratory)
- clubbing (especially in IPF and asbestosis)
- features of cor pulmonale
- note that signs and symptoms vary with underlying disease process
  • e.g. sarcoidosis is seldom associated with crackles and clubbing

Investigations

- CXR/high resolution CT (see Medical Imaging, MI7)
  • usually decreased lung volumes
  • reticular, nodular, or reticulonodular pattern (nodular <3 mm)
  • hilar/mediastinal adenopathy (especially in sarcoidosis)
- PFTs
  • restrictive pattern: decreased lung volumes and compliance
  • normal or increased FEV/FVC, e.g. flow rates are often normal or high when corrected for absolute lung volume
  • DLCO decreased due to V/Q mismatch (less surface area for gas exchange ± pulmonary vascular disease)
- ABGs
  • hypoxemia and respiratory alkalosis may be present with progression of disease
- other
  • bronchoscopy, bronchoalveolar lavage, lung biopsy
  • ESR, ANA (lupus), RF (RA), serum-precipitating antibodies to inhaled organic antigens (hypersensitivity pneumonitis), c-ANCA (GPA), anti-GBM (Goodpasture’s)

Unknown Etiologic Agents

IDIOPATHIC PULMONARY FIBROSIS

Definition

- also known as usual interstitial pneumonia or cryptogenic fibrosing alveolitis
- a progressive, irreversible condition characterized by fibrosis of lung parenchyma with no known cause
  • chest CT usually shows honeycomb lung, lung biopsy shows UIP (usual interstitial pneumonia) pattern
  • commonly presents over age 50, incidence rises with age; males > females
- DDx
  • other idiopathic interstitial pneumonia, especially NSIP, but also COP and
    • desquamative interstitial pneumonitis (DIP)
    • lymphocytic interstitial pneumonitis (LIP): usually 2nd to immune conditions such as HIV (mostly in children), Sjögren’s

Signs and Symptoms

- commonly presents over age 50, incidence rises with age; males > females
- dyspnea on exertion, nonproductive cough, constitutional symptoms, late inspiratory fine crackles at lung bases, clubbing

Investigations

- labs (nonspecific, autoimmune serology usually negative)
- CXR: reticular or reticulonodular pattern with lower lung predominance; may appreciate honeycombing in advanced disease
- high resolution CT: lower zone peripheral reticular markings, traction bronchiectasis, honeycombing; ground glass, consolidation, or nodules should not be prominent in IPF
- biopsy: rarely for UIP as honeycombing makes radiologic diagnosis possible

Treatment

- O₂
- N-acetylcysteine (anti-oxidant)
- pirfenidone and nintedanib may slow disease progression
- lung transplantation for advanced disease
- mean survival of 3-5 yr after diagnosis

SARCOIDOSIS

Definition

- idiopathic non-infectious granulomatous multi-system disease with lung involvement in 90%
- characterized pathologically by non-caseating granulomas
- numerous HLA antigens have been shown to play a role and familial sarcoidosis is now recognized
Epidemiology

• typically affects young and middle-aged patients
• higher incidence among African Americans and people at northern latitudes e.g. Scandinavia, Canada

Signs and Symptoms

• asymptomatic, cough, dyspnea, fever, arthralgia, malaise, erythema nodosum, chest pain
• chest exam often normal
• common extrapulmonary manifestations
  ▪ cardiac (arrhythmias, sudden death)
  ▪ eye involvement (anterior or posterior uveitis)
  ▪ skin involvement (skin papules, erythema nodosum, lupus pernio)
  ▪ peripheral lymphadenopathy
  ▪ arthralgia
  ▪ hepatomegaly ± splenomegaly
• less common extra-pulmonary manifestations involve bone, CNS, kidney
• two acute sarcoid syndromes
  ▪ Lofgren's syndrome: fever, erythema nodosum, bilateral hilar lymphadenopathy, arthralgias
  ▪ Heerfordt-Waldenstrom syndrome: fever, parotid enlargement, anterior uveitis, facial nerve palsy

Investigations

• CBC (cytopenias from spleen or marrow involvement)
• serum electrolytes, creatinine, liver enzymes, calcium (hypercalcemia/hypercalciuria due to vitamin D activation by granulomas)
• hypergammaglobulinemia, occasionally RF positive
• elevated serum ACE (non-specific and non-sensitive)
• CXR: predominantly nodular opacities especially in upper lung zones ± hilar adenopathy
• PFTs: normal, obstructive pattern, restrictive pattern with normal flow rates and decreased DLco, or mixed obstructive/restrictive pattern
• ECG: to rule out conduction abnormalities
• slit-lamp eye exam: to rule out uveitis

Diagnosis

• biopsy
  ▪ transbronchial lung biopsy, transbronchial lymph node aspiration, endobronchial ultrasound guided surgical (EBUS) biopsy, or mediastinoscopic lymph node biopsy for granulomas
  ▪ in ~75% of cases, transbronchial biopsy shows granulomas in the parenchyma even if the CXR is normal

Staging

• radiographic, based on CXR
  ▪ Stage 0: normal radiograph
  ▪ Stage I: bilateral hilar lymphadenopathy ± right paratracheal lymphadenopathy
  ▪ Stage II: bilateral hilar lymphadenopathy and diffuse interstitial disease
  ▪ Stage III: interstitial disease only (reticulonodular pattern or nodular pattern)
  ▪ Stage IV: pulmonary fibrosis (honeycombing)

Treatment

• 85% of stage I resolve spontaneously
• 50% of stage II resolve spontaneously
• steroids for symptoms, declining lung function, hypercalcemia, or involvement of eye, CNS, kidney, or heart (not for abnormal CXR alone)
• methotrexate or other immunosuppressives occasionally used

Prognosis

• approximately 10% mortality secondary to progressive fibrosis of lung parenchyma

Known Etiologic Agents

HYPERSENSITIVITY PNEUMONITIS

• also known as extrinsic allergic alveolitis
• non-IgE mediated inflammation of lung parenchyma (acute, subacute, and chronic forms)
• caused by sensitization to inhaled agents, usually organic dust
• pathology: airway-centered, poorly formed granulomas and lymphocytic inflammation
• exposure usually related to occupation or hobby
  ▪ Farmer's Lung (Thermophilic actinomycetes)
  ▪ Bird Breeder's/Bird Fancier's Lung (immune response to bird IgA)
  ▪ Humidifier Lung (Aureobasidium pullulans)
  ▪ Sauna Taker's Lung (Aureobasidium spp.)

Corticosteroids for Pulmonary Sarcoidosis

Cochrane DB Syst Rev 2005;CD001114
Study: Meta-analysis of 13 RCTs involving 1,986 participants examining the use of steroids (oral or inhaled) in sarcoidosis.
Results: Oral steroids demonstrated an improvement in CXR (RR 1.46, 95% CI 1.01-2.09). For inhaled corticosteroids, two studies showed no improvement in lung function and one study showed an improvement in diffusing capacity. No data on side-effects.
Conclusions: Oral steroids improve CXR findings and global scores of CXR, symptoms, and spirometry over 3-24 mo, but do not improve lung function or modify disease course. Oral steroids may be of benefit for patients with Stage 2 and 3 disease.
Signs and Symptoms
- acute presentation: (4-6 h after exposure)
  - dyspnea, cough, fever, chills, malaise (lasting 18-24 h)
  - CXR: diffuse infiltrates
- type III (immune complex) reaction
- subacute presentation: more insidious onset than acute presentation
- chronic presentation
  - insidious onset
  - dyspnea, cough, malaise, anorexia, weight loss
  - PFTs: progressively restrictive
- CXR: predominantly upper lobe reticulonodular pattern
- type IV (cell mediated, delayed hypersensitivity) reaction (see Rheumatology, RH2)
- in both acute and chronic reactions, serum precipitins may be detectable (neither sensitive nor specific)

Treatment
- early diagnosis: avoidance of further exposure is critical as chronic changes are irreversible
- systemic corticosteroids can relieve symptoms and speed resolution

PNEUMOCONIOSES
- reaction to inhaled inorganic dusts 0.5-5 µm in size
- no effective treatment, therefore key is exposure prevention through the use of protective equipment
- smoking cessation, annual influenza and pneumococcal vaccination, rehabilitation, lung transplant for endstage disease

Table 18. Pneumoconioses

<table>

<tbody>
<tr>
<td>Silicosis</td>
<td>At risk population: sandblasters, rock miners, stone cutters, quarry and highway workers. Generally requires &gt;20 yr exposure; may develop with much shorter but heavier exposure.</td>
<td>Dyspnea, cough, and wheezing</td>
<td>CXR: upper &gt; lower lobe. Early: nodular disease (simple pneumoconiosis), lung function usually normal. Late: nodules coalesce into masses (progressive massive fibrosis). Possible hilar lymph node enlargement (frequently calcified), especially “egg shell” calcification.</td>
<td>Mycobacterial infection (e.g. TB).</td>
</tr>
<tr>
<td>Coal Worker's Pneumoconiosis (CWP)</td>
<td>At risk population: coal workers, graphite workers. Coal and silica, coal is less fibrogenic than silica.</td>
<td>Pathologic hallmark is coal macule. Simple CWP. No signs or symptoms, usually normal lung function. Complicated CWP (also known as progressive massive fibrosis). Dyspnea Course: few patients progress to complicated CWP.</td>
<td>Simple CWP. CXR: multiple nodular opacities, mostly upper lobe. Complicated CWP. CXR: opacities larger and coalesce.</td>
<td>Caplan’s syndrome: rheumatoid arthritis and CWP present as larger nodules.</td>
</tr>
</tbody>
</table>

INTERSTITIAL LUNG DISEASE ASSOCIATED WITH DRUGS OR TREATMENTS

Drug-Induced
- antineoplastic agents: bleomycin, mitomycin, busulfan, cyclophosphamide, methotrexate, chlorambucil, BCNU (carmustine)
- antibiotics: nitrofurantoin, penicillin, sulfonamide
- cardiovascular drugs: amiodarone, tocainide
- anti-inflammatory agents: methotrexate, penicillamine
- gold salts
- illicit drugs (heroin, methadone)
- rituximab, anti-TNF-α agents (infliximab, etanercept, adalimumab)

Radiation-Induced
- early pneumonitis: approximately 6 wk post-exposure
- late fibrosis: 6-12 mo post-exposure
- infiltrates conform to the shape of the radiation field
Pulmonary Vascular Disease

Pulmonary Hypertension

Definition
- mean pulmonary arterial pressure >25 mmHg at rest and >30 mmHg with exercise, or a systolic pulmonary artery pressure of >40 mmHg at rest
- in the past, pulmonary HTN was classified as primary or secondary pulmonary HTN, but this classification was modified to a more clinically useful, treatment based classification

Table 19. World Health Organization Classification of Pulmonary Hypertension

<table>
<thead>
<tr>
<th>Classification</th>
<th>Some Causes</th>
<th>Treatment Options</th>

<td></td>
</tr>
<tr>
<td>V. Pulmonary HTN with Unclear Multifactorial Mechanisms</td>
<td>Hematologic disorders, Systemic disorders (e.g. sarcoidosis), Metabolic disorders, Exttrinsic compression of central pulmonary veins (tumour, adenopathy, fibrosing mediastinitis)</td>
<td>Treat underlying cause</td>
<td></td>
</tr>
</tbody>
</table>

Mechanisms of Pulmonary Hypertension (simplified)
- hypoxic vasoconstriction
  - chronic hypoxia causes pulmonary vasoconstriction by a variety of actions on the pulmonary artery endothelium and smooth muscle cells, such as: down regulation of endothelial nitric oxide synthase and alteration of voltage gated potassium channels leading to vasoconstriction
  - causes: COPD, chronic alveolar hypoxia
- decreased area of pulmonary vascular bed
  - leads to a rise in resting pulmonary arterial pressure
  - causes: collagen vascular disease, HIV infection, drugs and toxins, thrombotic or embolic disease, inflammatory, pulmonary capillary hemangiomatosis, interstitial fibrosis, CF
- volume and pressure overload
  - significant HTN only occurs with excessive volume overload, since pulmonary artery pressure will not rise until pulmonary blood flow exceeds 2.5x the basal rate
  - causes: congenital systemic-to-pulmonary shunts (e.g. VSD, ASD, PDA), portopulmonary HTN, left-sided heart conditions, pulmonary veno-occlusive disease, extrinsic compression of central pulmonary veins

Pulmonary arterial pressures are measured by pulmonary artery catheters (i.e. Swan-Ganz catheter) which are inserted into a large vein (often internal jugular). A balloon at the end of the catheter tip is inflated causing the catheter to advance through the right side of the heart and into the pulmonary artery. This allows for the measurement of RA, RV, PA, and pulmonary capillary wedge pressures as well as sampling of mixed venous blood. A thermostor near the end of the catheter also allows for assessment of cardiac output by thermodilution
IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION (PRIMARY PULMONARY HYPERTENSION)

Definition
- pulmonary HTN in the absence of a demonstrable cause
- exclude:
  - left-sided cardiac valvular disease
  - myocardial disease
  - congenital heart disease
  - any clinically significant parenchymal lung disease
  - systemic connective-tissue disease
  - chronic thromboembolic disease

Epidemiology
- usually presents in young females (20-40 yr); mean age of diagnosis is 36 yr
- most cases are sporadic; familial predisposition in 10% of cases, some linked to mutations in BMPR2
- may be associated with the use of anorexic drugs (e.g. Aminorex®, Fenfluramine*), amphetamines, and cocaine

Signs and Symptoms

<table>
<thead>
<tr>
<th>Symptoms</th>

<tr>
<td></td>
<td>Reynaud's phenomenon</td>
</tr>
</tbody>
</table>

Investigations
- CXR: enlarged central pulmonary arteries, cardiac changes due to RV enlargement (filling of retrosternal air space)
- ECG
  - RVH/right-sided strain (see Cardiology and Cardiac Surgery, C36)
- 2-D echo doppler assessment of right ventricular systolic pressure
- cardiac catheterization: direct measurement of pulmonary artery pressures (necessary to confirm diagnosis)
- PFTs to asses for underlying lung disease: DLCO usually reduced; volumes and flows normal
- CT angiogram to assess lung parenchyma and possible PE
- V/Q scan ± pulmonary angiogram to rule out thromboembolic disease
- serology: ANA positive in 30% of patients with primary pulmonary HTN; other serologic markers can be used in the appropriate clinical setting

Treatment
- see Table 19

Prognosis
- 2-3 yr mean survival from time of diagnosis
- survival decreases to approximately 1 yr if severe pulmonary HTN or right-heart failure

Pulmonary Embolism

Definition
- lodging of a blood clot in the pulmonary arterial tree with subsequent increase in pulmonary vascular resistance, impaired V/Q matching, and possibly reduced pulmonary blood flow

Etiology and Pathophysiology
- one of the most common causes of preventable death in the hospital
- proximal leg thrombi (popliteal, femoral, or iliac veins) are the source of most clinically recognized pulmonary emboli
- thrombi often start in calf, but must propagate into proximal veins to create a sufficiently large thrombus for a clinically significant PE
- fewer than 30% of patients have clinical evidence of DVT (e.g. leg swelling, pain, or tenderness)
- always suspect PE if patient develops fever, sudden dyspnea, chest pain, or collapse 1-2 wk after surgery

Guidelines for Vasodilator Response in Pulmonary Arterial HTN
- Patients with IPAH that respond to vasodilators acutely, have an improved survival with long-term use of CCBs
- Vasoreactivity testing: short-acting agent such as IV epoprostenol, IV adenosine, or inhaled NO
- Positive vasodilator response: mean PAP fall of at least 10 mm Hg to ≤40 mm Hg with an increased or unchanged cardiac output (European Society of Cardiology)
- Positive vasodilator response: should be considered as candidate for trial of oral CCB therapy

Medication Therapy for Pulmonary Arterial Hypertension. ACCP Evidence-Based Clinical Practice Guidelines. Chest 2004;126:35S-75S

Vircow's Triad
- Venous stasis
- Endothelial cell damage
- Hypercoagulable states

Multidetector Computed Tomography for Acute Pulmonary Embolism (PIOPED II Trial)
NEJM 2006;354:2317-2327
Study: Multicentre, prospective study investigating accuracy of computed tomography angiography (CTA alone and combined with venous phase imaging [CTA-CTV]) for the diagnosis of PE
Patients: 824 patients of several thousand eligible for study received reference diagnosis to confirm absence or presence of PE (V/Q scan, venous compression US of lower extremities, and pulmonary digital-subtraction angiography (DSA) if necessary). To confirm absence, patients in whom PE was excluded were telephoned 3-6 mo after enrollment. Any deaths were reviewed by an outcome committee. All patients enrolled also underwent clinical assessment of PE (including a Wells score) prior to imaging
Outcomes: Diagnosis of pulmonary embolism
Results: 773 of 824 patients had adequate CTA for interpretation. PE was diagnosed in 192 of the 824 patients. Sensitivity was 83% (150 of 181 patients; 95% CI 0.76-0.90) and specificity was 98% (567 of 592 patients; 95% CI 0.93-0.97). However, the predictive value of CTA-CTV varied when clinical pre-test probability was taken into account. PPV of CTA for high, intermediate and low clinical probability were 96% (95% CI 0.78-0.99), 92% (95% CI 0.84-0.98), and 54% (95% CI 0.40-0.70), respectively. NPV of CTA for high, intermediate and low clinical probability were 86% (95% CI 0.32-0.80), 89% (95% CI 0.82-0.93), and 96% (95% CI 0.82-0.98) respectively
Conclusion: CTA is effective for diagnosing or excluding PE in accordance with assessment of clinical pre-test probability. When clinical probability is inconsistent with imaging results, further investigations are required to rule out PE
Risk Factors
• stasis
  • immobilization: paralysis, stroke, bed rest, prolonged sitting during travel, immobilization of an extremity after fracture
• obesity, CHF
• chronic venous insufficiency
• endothelial cell damage
• post-operative injury, trauma
• hypercoagulable states
  • underlying malignancy (particularly adenocarcinoma)
  • cancer treatment (chemotherapy, hormonal)
  • exogenous estrogen administration (OCP, HRT)
• pregnancy, post-partum
• prior history of DVT/PE, family history
• nephrotic syndrome
  • coagulopathies: Factor V Leiden, Prothrombin 20210A variant, inherited deficiencies of antithrombin/protein C/protein S, antiphospholipid antibody, hyperhomocysteinemia, increased Factor VIII levels, and myeloproliferative disease
• increasing age

Investigations (if highly suspicious, go straight to CT angiogram)
• see Emergency Medicine, ER32

<tr>
<th>Clinical Prediction Rule for Pulmonary Embolism</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Clinical Probability</strong></td>
</tr>
<tr>
<td>Low (0–2)</td>
</tr>
<tr>
<td>Intermediate (3–6)</td>
</tr>
<tr>
<td>High (&gt;6)</td>
</tr>
</tbody>
</table>

D-dimer is elevated in patients with recent surgery, cancer, inflammation, infection, and severe renal dysfunction. It has good sensitivity and negative predictive value, but poor specificity and positive predictive value.

Evaluation of a Suspected Pulmonary Embolism
Low clinical probability of embolism

\[
\text{D-dimer (–ve) \rightarrow CT scan (–ve) \rightarrow ruled out (–ve)} \rightarrow \text{ruled out (–ve)} \\
\text{Intermediate or high probability} \\
\text{CT scan (+ve) \rightarrow ruled out (+ve) \rightarrow ruled in (+ve)} \rightarrow \text{ruled in (+ve)} \\
\]

Notes
• Use D-dimers only if low clinical probability, otherwise, go straight to CT.
• If using V/Q scans (CT contrast allergy or renal failure):
  • Negative V/Q scan rules out the diagnosis
  • High probability V/Q scan only rules in the diagnosis if high clinical suspicion
  • Inconclusive V/Q scan requires leg U/S to look for DVT or CT.
Treatment
- admit for observation (patients with DVT only are often sent home on LMWH)
- oxygen: supplemental O₂ if hypoxic or short of breath
- pain relief: analgesics if chest pain – narcotics or acetaminophen
- acute anticoagulation: therapeutic-dose SC LMWH or IV heparin – start ASAP
  - anticoagulation stops clot propagation, prevents new clots and allows endogenous fibrinolytic system to dissolve existing thromboemboli over months
- get baseline CBC, INR, aPTT ± renal function ± liver function
- for SC LMWH: dalteparin 200 U/kg once daily, enoxaparin 1 mg/kg bid or 1.5mg/kg once daily, or tinzaparin 175 U/kg once daily – no lab monitoring – avoid or reduce dose in renal dysfunction
- for IV heparin: bolus of 75 U/kg (usually 5,000 U) followed by infusion starting at 20 U/kg/h – aim for aPTT 2-3x control
- long-term anticoagulation
  - warfarin: start the same day as LMWH/heparin – overlap warfarin with LMWH/heparin for at least 5 d and until INR in target range of 2-3 for at least 2 d
  - LMWH instead of warfarin for pregnancy, active cancer, or high bleeding risk patients
  - direct thrombin inhibitors: can treat from outset with rivaroxaban; dabigatran has been shown to have lower bleeding risk than warfarin; no monitoring required, however agents not reversible, so avoid if bleeding concerns
- IV thrombolytic therapy
  - if patient has massive PE (hypotension or clinical right heart failure) and no contraindications
  - hastens resolution of PE but may not improve survival or long-term outcome and doubles risk of major bleeding
- interventional thrombolytic therapy
  - massive PE is preferentially treated with catheter-directed thrombolysis by an interventional radiologist
  - works better than IV thrombolytic therapy and fewer contraindications
- IVC filter: only if recent proximal DVT + absolute contraindication to anticoagulation
- duration of long-term anticoagulation: individualized, however generally
  - if reversible cause for PE (surgery, injury, pregnancy, etc.): 3-6 mo
  - if PE unprovoked: 6 mo to indefinite
  - if ongoing major risk factor (active cancer, antiphospholipid antibody, etc.): indefinite

Thromboprophylaxis
- mandatory for most hospital patients: reduces DVT, PE, all-cause mortality, cost-effective
- start ASAP
- continue at least until discharge or recommend extending for 35 d post-operatively, if major orthopedic surgery

PE Rule Out Criteria (PERC)
Prospective Multicentre Evaluation of the Pulmonary Embolism Rule Out Criteria
J Thorac Oncol 2009;6:172
- Age less than 50 yr
- Heart rate less than 100 bpm
- Oxyhemoglobin saturation ≥95 percent
- No hemoptysis
- No estrogen use
- No prior DVT or PE
- No unilateral leg swelling
- No surgery or trauma requiring hospitalization within the past 4 wk

Acute PE can probably be excluded without further diagnostic testing if the patient meets all PERC criteria AND there is a low clinical suspicion for PE, according to either the Wells’ criteria or a low gestalt probability determined by the clinician prior to diagnostic testing for PE.

Extended Use of Dabigatran, Warfarin or Placebo in Venous Thromboembolism
NEJM 2013;368:709-718
Study: Two double blind, RCTs; one comparing against placebo, the other against active treatment.
Population: 4,199 patients (2,856 in active-control study, 1,343 in placebo-control study) with VTE who had completed at least 3 mo of therapy.
Intervention: In the active-control study, patients randomized to either 150 mg dabigatran or warfarin (INR 2.0-3.0). Patients in the placebo-control study received either 100 mg dabigatran or placebo.
Outcome: Recurrence of VTE, risk of major or clinically relevant bleed.
Results: In the active-control study, there was a hazard ratio (HR) of 1.14 (95% CI 0.79-1.64 for non-inferiority) of recurrent VTE with dabigatran vs. warfarin. HR of major or clinically relevant bleed was 0.94 (95% CI 0.47-1.81). In the placebo-control study, the HR of VTE with dabigatran vs. placebo was 0.09 (95% CI 0.02-0.25). HR of major or clinically relevant bleed was 2.92 (95% CI 1.53-5.60).
Conclusions: Dabigatran appears to be non-inferior to warfarin in the prevention of VTE recurrence. Dabigatran is associated with a lower risk of major or clinically relevant bleed than warfarin, but greater than placebo.

Malignancy Workup: 12% of patients with idiopathic VTE will have a malignancy.

The Use of Unfractionated Heparin Should Be Limited to:
- Patients with severe renal dysfunction (CrCl < 30 ml/min) in whom LMWH and novel oral anticoagulation should be avoided
- Patients at elevated risk of bleeding that may need rapid reversal of anticoagulation
- Patients who receive thrombolytic therapy

Goodpasture’s Disease is the most common collagen vascular disease affecting the lung

Differential of an Anterior Compartment Mass
- 4 Ts
  - Thymoma
  - Thyroid enlargement (goitre)
  - Teratoma
  - Tumours (lymphoma, parathyroid, esophageal, angiomaticus)

Mediastinal Components
- Anterior: sternum to pericardium and great vessels. Includes: thymus, extrapericardial aorta and branches, great veins, lymphatic tissues
- Middle: pericardium (anteriorly), posterior pericardial reflection, diaphragm, thoracic inlet. Includes: heart, intrapericardial great vessels, pericardium, trachea
- Posterior: posterior pericardial reflection, posterior border of vertebral bodies, first rib to the diaphragm. Includes: esophageus, vagus nerve, thoracic duct, sympathetic chain,azygos venous system

Horners Syndrome
Ptosis, Miosis, Anhydrosis

Scleroderma is the most common collagen vascular disease affecting the lung

Diseases of the Mediastinum and Pleura

Mediastinal Masses

Definition
- mediastinum: bound by the thoracic inlet, diaphragm, sternum, vertebral bodies, and the pleura
- can be broken down into 3 compartments: anterior, middle, and posterior

Etiology and Pathophysiology
- diagnosis is aided by location and patient’s age
- anterior compartment: more likely to be malignant
  - “Four Ts” (see sidebar), lymphoma, lipoma, pericardial cyst
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumour, lymphoma, lymph node enlargement, aortic aneurysm
- posterior compartment
  - neurogenic tumours, meningocele, enteric cysts, lymphoma, diaphragmatic hernias, esophageal tumour, aortic aneurysm

Signs and Symptoms
- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner’s syndrome, facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes (e.g. myasthenia gravis [thymomas])

Investigations
- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumours
- U/S (best for assessment of structures in close proximity to the heart and pericardium)
- radionuclide scanning: 131I (for thyroid), gallium (for lymphoma)
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, ß-hCG
- biopsy (mediastinoscopy, percutaneous needle aspiration)
Management
• excision if symptomatic enlarging benign masses or concerns of malignancy
• resect bronchogenic cysts and localized neurogenic tumours via minimally invasive video assisted procedures
• exploration via sternotomy or thoracotomy
• diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumour, or unresectable invasive malignancy
• ± post-operative radiotherapy/chemotherapy if malignant

Mediastinitis
• most common causes: post-operative complications of cardiovascular or thoracic surgical procedures

Acute
• etiology
  ▪ complication of endoscopy (e.g. esophageal perforation providing entry point for infection)
  ▪ esophageal or cardiac surgery
  ▪ tumour necrosis
• signs and symptoms
  ▪ fever, substernal pain
  ▪ pneumomediastinum, mediastinal compression
  ▪ Hamman's sign (auscultatory “crunch” during cardiac systole)
• treatment
  ▪ antibiotics, drainage, ± surgical closure of perforation

Chronic
• usually granulomatous process or fibrosis related to previous infection (e.g. histoplasmosis, TB, sarcoidosis, syphilis)

Pleural Effusions
Definition
• excess amount of fluid in the pleural space (normally up to 25 mL)

Etiology
• disruption of normal equilibrium between pleural fluid formation/entry and pleural fluid absorption/exit
• pleural effusions are classified as transudative or exudative
  ▪ distinguish clinically using Light's Criteria, which has a sensitivity of 98% and specificity of 83% for identifying exudative pleural effusions

Table 24. Laboratory Values in Transudative and Exudative Pleural Effusion

</tr>
<tr>
<td>Pleural LDH</td>
<td>&gt;2/3 upper limit of N serum LDH</td>
</tr>
</tbody>
</table>

Exudate = at Least One Criterion Met

Transudative Pleural Effusions
• pathophysiology: alteration of systemic factors that affect the formation and absorption of pleural fluid (e.g. increased capillary hydrostatic pressure, decreased plasma oncotic pressure)
• etiology
  ▪ CHF: usually right-sided or bilateral cirrhosis
  ▪ nephrotic syndrome, protein losing enteropathy, cirrhosis
  ▪ pulmonary embolism (may cause transudative but more often causes exudative effusion)
  ▪ peritoneal dialysis, hypothyroidism, CF, urinothorax

Exudative Pleural Effusions
• pathophysiology: increased permeability of pleural capillaries or lymphatic dysfunction
• etiology (see Table 25)
Table 25. Exudative Pleural Effusion Etiologies

Other causes:

- Collagen vascular diseases: RA, SLE, PAN, Sjögren's syndrome, systemic lupus erythematosus
- Pulmonary embolism
- Post-CABG
- Drug reaction
- Intra-Abdominal:
  - Subphrenic abscess
  - Pancreatic disease (elevated pleural fluid amylase)
  - Meigs' syndrome (ascites and hydrothorax associated with an ovarian fibroma or other pelvic tumour)
- Intra-Thoracic:
  - Esophageal perforation (elevated fluid amylase)
- Trauma
  - Chylothorax: thoracic duct disrupted and chyle accumulates in the pleural space due to trauma, tumour
  - Hemothorax: rupture of a blood vessel, commonly by trauma or tumours
  - Pneumothorax (spontaneous, traumatic, tension)
- Malignancy:
  - Lung carcinoma (35%)
  - Lymphoma (10%)
  - Metastases: breast (25%), ovary, kidney
  - Mesothelioma
- Inflammatory:
  - Collagen vascular diseases: RA, SLE
  - Pulmonary embolism
  - Post-CABG
  - Drug reaction
- Intra-Abdominal:
  - Subphrenic abscess
  - Pancreatic disease (elevated pleural fluid amylase)
  - Meigs' syndrome (ascites and hydrothorax associated with an ovarian fibroma or other pelvic tumour)
- Intra-Thoracic:
  - Esophageal perforation (elevated fluid amylase)
- Trauma
  - Chylothorax: thoracic duct disrupted and chyle accumulates in the pleural space due to trauma, tumour
  - Hemothorax: rupture of a blood vessel, commonly by trauma or tumours
  - Pneumothorax (spontaneous, traumatic, tension)
- Malignancy:
  - Lung carcinoma (35%)
  - Lymphoma (10%)

  - Meigs' syndrome (ascites and hydrothorax associated with an ovarian fibroma or other pelvic tumour)
- Intra-Thoracic:
  - Esophageal perforation (elevated fluid amylase)
- Trauma
  - Chylothorax: thoracic duct disrupted and chyle accumulates in the pleural space due to trauma, tumour
  - Hemothorax: rupture of a blood vessel, commonly by trauma or tumours
  - Pneumothorax (spontaneous, traumatic, tension)
- Malignancy:
  - Lung carcinoma (35%)
  - Lymphoma (10%)
  - Metastases: breast (25%), ovary, kidney
  - Mesothelioma
- Inflammatory:
  - Collagen vascular diseases: RA, SLE
  - Pulmonary embolism
  - Post-CABG
  - Drug reaction
- Intra-Abdominal:
  - Subphrenic abscess
  - Pancreatic disease (elevated pleural fluid amylase)
  - Meigs' syndrome (ascites and hydrothorax associated with an ovarian fibroma or other pelvic tumour)
- Intra-Thoracic:
  - Esophageal perforation (elevated fluid amylase)
- Trauma
  - Chylothorax: thoracic duct disrupted and chyle accumulates in the pleural space due to trauma, tumour
  - Hemothorax: rupture of a blood vessel, commonly by trauma or tumours
  - Pneumothorax (spontaneous, traumatic, tension)

Signs and Symptoms

- Often asymptomatic
- Dyspnea: varies with size of effusion and underlying lung function
- Pleuritic chest pain
- Inspection: trachea deviates away from effusion, ipsilateral decreased expansion
- Percussion: decreased tactile fremitus, dullness
- Auscultation: decreased breath sounds, bronchial breathing and egophony at upper level, pleural friction rub

Investigations

- **CXR**
  - Must have >200 mL of pleural fluid for visualization on PA film
  - Lateral: >50 mL leads to blunting of posterior costophrenic angle
  - Dense opacification of lung fields with concave meniscus
  - Decubitus: fluid will shift unless it is loculated
  - Supine: fluid will appear as general haziness
- **CT may be helpful in differentiating parenchymal from pleural abnormalities, may identify underlying lung pathology**
- **U/S** detects small effusions and can guide thoracentesis
- **Thoracentesis is indicated if pleural effusion is a new finding; be sure to send off blood work (LDH, glucose, protein) at the same time for comparison**
  - Risk of re-expansion pulmonary edema if >1.5 L of fluid is removed
  - Inspect for colour, character, and odour of fluid
  - Analyze fluid
- **pleural biopsy**: indicated if suspect TB, mesothelioma, or other malignancy (and if cytology negative)
- ± U/S: detects small effusions and can guide thoracentesis
- **Treatment depends on cause, ± drainage if symptomatic**
- **CT can be helpful in differentiating parenchymal from pleural abnormalities**

Treatment
- thoracentesis
- treat underlying cause
- consider indwelling pleural catheter or pleurodesis in refractory effusions

Complicated Parapneumonic Effusion
- persistent bacteria in the pleural space but fluid is non-purulent
- neutrophils, pleural fluid acidosis (pH < 7.00), and high LDH
- often no bacteria grown since rapidly cleared from pleural space
- fibrin layer leading to loculation of pleural fluid
- treatment: antibiotics and drainage, treat as an empyema

Empyema

Definition
- pus in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent)
- positive culture is not required for diagnosis

Etiology
- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g. trauma, surgery)

Signs and Symptoms
- fever, pleuritic chest pain

Investigations
- CT chest
- thoracentesis
- PMNs (lymphocytes in TB) ± visible organisms on Gram stain

Treatment
- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with video-assisted thoroscopic surgery (VATS), or surgical removal of fibrin coating to allow lung re-expansion (decortication)

Atelectasis
- see General Surgery, GS10

Pneumothorax

Definition
- presence of air in the pleural space

Pathophysiology
- entry of air into pleural space raises intrapleural pressure causing partial lung deflation

Etiology
- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic (central venous catheter, thoracentesis, mechanical ventilation with barotrauma)
- spontaneous (no history of trauma)
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb of lung into pleural space
    - predominantly tall, healthy, young males
  - secondary (underlying lung disease)
    - rupture of subpleural bleb which migrates along bronchialveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface (e.g. pneumonia, abscess, PCP, lung CA, emphysema)

Signs and Symptoms
- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
tachypnea, tachycardia
- tracheal deviation (contralateral deviation in tension pneumothorax)
- ipsilateral diminished chest expansion
- decreased tactile/vocal fremitus
- hyperresonance
- ipsilateral diminished breath sounds

**Investigations**
- CXR
  - small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  - large: increased density and decreased volume of lung on side of pneumothorax
  - see Medical Imaging, MI8

**Treatment**
- small pneumothoraces (<20% with no signs of respiratory/circulatory collapse) resolve spontaneously; breathing 100% oxygen accelerates resorption of air
- small intercostal tube with Heimlich valve for most spontaneous pneumothoraces
- large pneumothoraces or those complicating underlying lung disease require placement of a chest tube connected to underwater seal ± suction
- for repeated episodes: pleurodesis with sclerosing agent or apical bullectomy and abrasion
- treat underlying cause (e.g. antibiotic for PCP)

### Asbestos-Related Pleural Disease and Mesothelioma

**Etiology and Pathophysiology**
- benign manifestations of asbestos exposure
  - “benign asbestos pleural effusion”
  - exudative effusion, typically ~10 yr after exposure, resolves
  - pleural plaques, usually calcified
  - marker of exposure; usually an asymptomatic radiologic finding
- mesothelioma
  - primary malignancy of the pleura
  - decades after asbestos exposure (even with limited exposure)
  - smoking not a risk factor, but asbestos and smoking synergistically increase risk of lung cancer

**Signs and Symptoms**
- persistent chest pain, dyspnea, cough, bloody pleural effusion, weight loss

**Investigations**
- biopsy (pleuroscopic or open)
- needle biopsy may seed needle tract with tumour

**Treatment**
- resection (extrapleural pneumonectomy) requires careful patient selection; rarely successful (average survival <1 yr)

### Respiratory Failure

**Definition**
- failure of respiratory system to maintain normal blood gases
- hypoxemic ($P_O_2 < 60$ mmHg)
- hypercapnic ($P_CO_2 > 50$ mmHg)
- acute vs. chronic (compensatory mechanisms activated)

**Signs and Symptoms**
- signs of underlying disease
- hypoxemia: restlessness, confusion, cyanosis, coma, cor pulmonale
- hypercapnia: headache, dyspnea, drowsiness, asterixis, warm periphery, plethora, increased ICP (secondary to vasodilatation)

**Investigations**
- serial ABGs
- CXR and/or CT, bronchoscopy to characterize underlying cause if unclear
Hypoxemic Respiratory Failure

Definition
- PaO₂ decreased, PaCO₂ normal or decreased

Treatment
- reverse the underlying pathology
- oxygen therapy: maintain oxygenation (if shunt present, supplemental O₂ is less effective; see Anesthesia, A9, for oxygen delivery systems)
- ventilation, BiPAP, and PEEP/CPAP (see Anesthesia, A10): positive pressure can recruit alveoli and redistribute lung fluid
- improve cardiac output: ± hemodynamic support (fluids, vasopressors, inotropes), reduction of O₂ requirements

<table>
<thead>
<tr>

</tr>
<tr>
<td>5. V/Q Mismatch</td>
</tr>
<tr>
<td>6. Diffusion Impairment</td>
</tr>
</tbody>
</table>

In chronic hypercapnia, supplemental O₂ may decrease the hypoxic drive to breathe, but do not deny oxygen if the patient is hypoxic

Hypercapnic Respiratory Failure

- PaCO₂ increased, PaO₂ decreased

Pathophysiology
- increased CO₂ production: fever, sepsis, seizure, acidosis, carbohydrate load
- alveolar hypoventilation: COPD, asthma, CF, chest wall disorder, dead space ventilation (rapid shallow breathing)  
  - inefficient gas exchange results in inadequate CO₂ removal in spite of normal or increased minute volume
- hypoventilation
  - central: brainstem stroke, hypothyroidism, severe metabolic alkalosis, drugs (opiates, benzodiazepines)
  - neuromuscular: myasthenia gravis, Guillain-Barré, phrenic nerve injury, muscular dystrophy, polymyositis, kyphoscoliosis
  - muscle fatigue

Treatment
- reverse the underlying pathology
- if PaCO₂ >50 mmHg and pH is acidemic consider noninvasive or mechanical ventilation
- correct exacerbating factors
  - NTT/ETT suction: clearance of secretions
  - bronchodilators: reduction of airway resistance
  - antibiotics: treatment of infections
- maintain oxygenation (see above)
- diet: increased carbohydrate can increase PaCO₂ in those with mechanical or limited alveolar ventilation; high lipids decrease PaCO₂

Dead Space
- Ventilation without perfusion
- The opposite of shunt

Causes of Hypercapnia
- High Inspired CO₂
- Low Total Ventilation
- High Deadspace Ventilation
- High CO₂ Production

In COPD patients with chronic hypercapnia (“CO₂ retainers”), provide supplemental oxygen to achieve target SaO₂ from 88-92%
Acute Respiratory Distress Syndrome

- clinical syndrome characterized by severe respiratory distress, hypoxemia, and noncardiogenic pulmonary edema
- The Berlin Criteria (JAMA 2012; 307:2526-2533) for ARDS
  - acute onset
    - within 7 d of a defined event, such as sepsis, pneumonia, or patient noticing worsening of respiratory symptoms
      - usually occurs within 72 h of presumed trigger
  - bilateral opacities consistent with pulmonary edema on either CT or CXR
  - not fully explained by cardiac failure/fluid overload, but patient may have concurrent heart failure
  - objective assessment of cardiac function (e.g. echocardiogram) should be performed even if no clear risk factors

Etiology
- direct lung injury
  - airway: aspiration (gastric contents, drowning), pneumonia, inhalation injury (oxygen toxicity, nitrogen dioxide, smoke)
  - circulation: embolism (fat, amniotic fluid), reperfusion injury
- indirect lung injury
  - circulation: sepsis, shock, trauma, blood transfusion, pancreatitis
  - neurogenic: head trauma, intracranial hemorrhage, drug overdose (narcotics, sedatives, TCAs)

Pathophysiology
- disruption of alveolar capillary membranes \(\rightarrow\) leaky capillaries \(\rightarrow\) interstitial and alveolar pulmonary edema \(\rightarrow\) reduced compliance, V/Q mismatch, shunt, hypoxemia, pulmonary HTN

Clinical Course
A. Exudative Phase
- first 7 d of illness after exposure to ARDS precipitant
- alveolar capillary endothelial cells and type I pneumocytes are injured, resulting in loss of normally tight alveolar barrier
- patients develop dyspnea, tachypnea, increased work of breathing
  - these result in respiratory fatigue and eventually respiratory failure (see Hypoxemic Respiratory Failure, R26)

B. Fibroproliferative Phase
- after day 7
  - may still experience dyspnea, tachypnea, fatigue, and hypoxemia
  - most patients clinically improve and are able to wean off mechanical ventilation
  - some patients develop fibrotic lung changes that may require long-term support on supplemental oxygen or even mechanical ventilation
  - if fibrosis present, associated with increased mortality

Treatment
- based on ARDS network (see Landmark Respirology Trials, R36)
- treat underlying disorder (e.g. antibiotics if infection present)
- mechanical ventilation using low tidal volumes (<6 mL/kg) to prevent barotrauma
  - use optimal amount of PEEP (positive end-expiratory pressure) to keep airways open and allow the use of lower F\textsubscript{O\textsubscript{2}}
  - may consider using prone ventilation, and/or inhaled nitric oxide, high frequency oscillator or ECMO (extracorporeal membrane oxygenation) if conventional treatment is failing
- fluids and inotropic therapy (e.g. dopamine, vasopressin) if cardiac output inadequate
- pulmonary-arterial catheter now seldom used for monitoring hemodynamics
- mortality: 30–40%, usually due to non-pulmonary complications
- sequelae of ARDS include residual pulmonary impairment, severe debilitation, polyneuropathy and psychologic difficulties, which gradually improve over time
- most survivors eventually regain near-normal lung function, often with mildly reduced diffusion capacity

Lung Cancer

Classification
- Lung tumours can be classified as primary or secondary, benign or malignant, endobronchial or parenchymal.
- Bronchogenic carcinoma (epithelial lung tumours) is the most common type of primary lung tumour (other types make up less than 1%).
  - Small cell lung cancer (SCLC): 10-15%
  - Non-small-cell lung cancer (NSCLC): 85-90%
- Squamous cell carcinoma: arise from the proximal respiratory epithelium.
- Adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
- Bronchoalveolar carcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring.
- Large cell undifferentiated cancer: diagnosis of exclusion.
- Benign epithelial lung tumours can be classified as papillomas or adenomas.

Risk Factors
- Cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers.
- Other risk factors include: tobacco smoking, pipe smoking, second-hand smoke, asbestos, and exposure to asbestos.
- Risks associated with smoking include: chronic cough, hoarseness, lung cancer, and chronic obstructive pulmonary disease.
- Risks associated with asbestos exposure include: lung cancer, mesothelioma, and asbestosis.

Signs and Symptoms
- May be due to primary lesion, metastasis, or paraneoplastic syndrome.
- Primary lesion: cough, dyspnea, chest pain, hemoptysis.
- Metastasis: bone pain, weight loss, fever, anemia.
- Paraneoplastic syndromes: anorexia, weight loss, fever, anemia.

Summary of Recommendations on Screening for Lung Cancer

| American College of Chest Physicians (2013) | Screening with CXR | Not recommended |
| American Lung Association (2013)           | Screening with CXR | Not recommended |

Reduced Lung Cancer Mortality with Low-Dose CT Screening

| Study: Multicentre, RCT. | Methods: 2,058 participants at high risk for lung cancer (55-74 yr, >30 yr smoking), and smoking cessation for <5 y | Low-dose CT |
| Study: Multicentre, RCT. | Rate of positive screening test 24.2% 6.9% |
| Study: Multicentre, RCT. | False positives 96.4% 94.5% |
| Study: Multicentre, RCT. | Incidence of lung cancer Death from lung cancer |
| Study: Multicentre, RCT. | Person yr | Person yr |
| Study: Multicentre, RCT. | Person yr | Person yr |
| Conclusions: Screening with low-dose CT reduces mortality from lung cancer. |

### Investigations

- **Initial diagnosis**
  - Imaging: CXR, CT chest + upper abdomen, PET scan, bone scan
  - Cytology: sputum
  - Biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy, mediastinoscopy
- **Staging workup**
  - TMN staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  - Blood work: electrolytes, LFTs, calcium, ALP
  - Imaging: CXR, CT thorax and upper abdomen, bone scan, neuroimaging
  - Invasive: bronchoscopy (EBUS), mediastinoscopy, mediastinotomy, thoracotomy
  - Screen adenocarcinoma for EGFR and ALK mutations

* Depending on clinical vs. pathologic stage.*

### Treatment

- Options include surgery, radiotherapy, chemotherapy, and palliative care for end-stage disease.
- Surgery not usually performed for SCLC since it is generally non-curable.
- Contraindications for surgery:
  - Spread to contralateral lymph nodes or distant sites
  - Patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases.
  - Poor pulmonary status (e.g., unable to tolerate resection of lung).

### Prevention

- Smoking cessation
- Avoidance of exposures
- Early detection

Malignant lung tumours are the most common cause of cancer mortality throughout the world in both men and women.
• chemotherapy (used in combination with other treatments)
  ▪ common agents: etoposide, platinum agents (e.g. cisplatinum), ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  ▪ complications
    • acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
    • chronic: neurologic damage, leukemia, additional primary neoplasms

**Approach to the Solitary Pulmonary Nodule**

• see Medical Imaging, MI7

**Definition**

• a round or oval, sharply circumscribed radiographic lesion up to 3-4 cm, which may or may not be calcified, and is surrounded by normal lung

• can be benign or malignant

**Table 31. Differential Diagnosis for Benign vs. Malignant Solitary Nodule**

</tr>
</tbody>
</table>

**Investigations**

• CXR: always compare with previous CXR
• CT densitometry and contrast enhanced CT of thorax
• sputum cytology: usually poor yield
• biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy or thoracotomy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  ▪ if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  ▪ if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
• watchful waiting: repeat CXR and/or CT scan at 3, 6, 12 mo
• PET scan can help distinguish benign from malignant nodules

**Table 32. CXR Characteristics of Benign vs. Malignant Solitary Nodule**

</tr>
<tr>
<td>Doubling Time</td>
<td>Doubles in &lt;1 mo or &gt;2 yr</td>
<td>Doubles in &gt;1 mo or &lt;2 yr</td>
</tr>
</tbody>
</table>

**Terminology**

• "nodule" <3 cm
• "mass" >3 cm

**Hamartomas**

• 10% of benign lung lesions
• Composed of tissues normally present in lung (fat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth
• Peak incidence is age 60, more common in men
• Usually peripheral and clinically silent
• CXR shows clustered "popcorn" pattern of calcification (pathognomonic for hamartoma)

Pulmonary neoplasms may present as a solitary pulmonary nodule identified incidentally on a radiographic study (~10% of cases) or as symptomatic disease (most cases)

Adenocarcinoma present in a non-smoker may be due to endothelial growth factor receptor mutation

Corona Radiata Sign on Chest CT

• Fine striations that extend linearly from a nodule in a spiculated fashion
• Highly associated with malignancy
Sleep-Related Breathing Disorders

Hypoventilation Syndromes

- primary alveolar hypoventilation: idiopathic
- obesity-hypoventilation syndrome (Pickwickian syndrome)
- respiratory neuromuscular disorders

Sleep Apnea

Definition
- episodic decreases in airflow during sleep
- quantitatively measured by the Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep
- sleep apnea generally accepted to be present if AHI >15

Classification
- obstructive (OSA)
  - caused by transient, episodic obstruction of the upper airway
  - absent or reduced airflow despite persistent respiratory effort
- central (CSA) (see Neurology, N49)
  - caused by transient, episodic decreases in CNS drive to breathe
  - no airflow because no respiratory effort
  - Cheyne-Stokes Respiration: a form of CSA in which central apneas alternate with hyperpneas to produce a crescendo-decrescendo pattern of tidal volume; seen in severe LV dysfunction, brain injury, and other settings (see Figure 2)
- mixed (MSA)
  - features of both OSA and CSA
  - loss of hypoxic and hypercapnic drives to breathe secondary to “resuscitative breathing”: overcompensatory hyperventilation upon awakening from OSA induced hypoxia

Risk Factors
- for OSA: obesity, upper airway abnormality, neuromuscular disease, hypothyroidism, alcohol/sedative use, nasal congestion, sleep deprivation
- for CSA: LV failure, brainstem lesions, encephalitis, encephalopathy, myxedema, high altitude

Signs and Symptoms
- obtain history from spouse/partner
- secondary to repeated arousals and fragmentation of sleep: daytime somnolence, personality and cognitive changes, snoring
- secondary to hypoxemia and hypercapnia: morning headache, polycythemia, pulmonary/systemic HTN, cor pulmonale/CHF, nocturnal angina, arrhythmias

Stage and treat
Treat cause
Biopsy or resect for diagnosis

Carcinoids
- Early onset (40-60 yr)
- Most are central and can produce symptoms and signs of bronchial obstruction
- Hemoptysis is present in ~50% of cases

Normal Respiratory Changes during Sleep
- Tidal volume decreases
- Arterial CO₂ increases (due to decreased minute ventilation)
- Pharyngeal dilator muscles relax causing increased upper airway resistance

Apnea: absence of breathing for ≥10 s
Hypopnea: excessive decrease in rate or depth of breathing (>50% reduction in ventilation)
Hypercnea: excessive increase in rate or depth of breathing
• the typical presentation for OSA is a middle-aged obese male who snores
• CSA can be due to neurological disease

Investigations
• sleep study (polysomnography)
  • evaluates sleep stages, airflow, ribcage movement, ECG, SaO₂, limb movements
• indications
  • excessive daytime sleepiness
  • unexplained pulmonary HTN or polycythemia
  • daytime hypcapnia
  • titration of optimal nasal CPAP
  • assessment of objective response to other interventions

Treatment
• modifiable factors: weight loss, decreased alcohol/sedatives, nasal decongestion, treatment of underlying medical conditions
• OSA or MSA: nasal CPAP, postural therapy (e.g. no supine sleeping), dental appliance, uvulopalatopharyngoplasty, tonsillectomy
• CSA or hypventilation syndromes: nasal BiPAP/CPAP, respiratory stimulants (e.g. progesterone) in select cases
• tracheostomy rarely required and should be used as last resort for OSA

Complications
• depression, weight gain, decreased quality of life, workplace and vehicular accidents, cardiac complications (e.g. HTN), reduced work/social function

Introduction to Intensive Care

• goal is to provide stabilization for critically ill patients: hemodynamic, respiratory or cardiac instability, or need for close monitoring

Intensive Care Unit Basics

Lines and Catheters
• arterial lines
  • monitor beat-to-beat blood pressure variations, obtain blood for routine ABGs
  • common sites are the radial and femoral arteries
• central venous catheter (central line)
  • administer IV fluids, monitor CVP, insert pulmonary artery catheters
  • administer TPN and agents too irritating for peripheral line
  • common sites: internal jugular vein, subclavian vein, femoral vein
• pulmonary arterial catheter
  • balloon guides the catheter from a major vein to the right heart
  • measures pulmonary capillary wedge pressure (PCWP) via a catheter wedged in distal pulmonary artery
  • PCWP reflects the LA and LV diastolic pressure (barring pulmonary venous or mitral valve disease)
• indications (now used infrequently due to associated complications)
  • diagnosis of shock states, primary pulmonary HTN, valvular disease, intracardiac shunts, cardiac tamponade, PE
  • assessment of hemodynamic response to therapies
  • differentiation of high- versus low-pressure pulmonary edema
  • management of complicated MI, multiorgan system failure and/or severe burns, or hemodynamic instability after cardiac surgery
• absolute contraindications
  • tricuspid or pulmonary valve mechanical prosthesis
  • right heart mass (thrombus or tumour)
  • tricuspid or pulmonary valve endocarditis

</tbody>
</table>

### Shock

- **see** [Emergency Medicine](#), ER3
- inadequate tissue perfusion potentially resulting in end organ injury
  - categories of shock
    - hypovolemic: hemorrhage, dehydration, vomiting, diarrhea, interstitial fluid redistribution
    - cardiogenic: myopathic (myocardial ischemia ± infarction), mechanical, arrhythmic, pharmacologic
    - obstructive: massive PE (saddle embolus), pericardial tamponade, constrictive pericarditis, increased intrathoracic pressure (e.g. tension pneumothorax)
    - distributive: sepsis, anaphylactic reaction, neurogenic, endocrinologic, toxic

**Table 35. Changes Seen in Different Classes of Shock**

<td>Look for obvious signs of infection or anaphylaxis</td>
</tr>
</tbody>
</table>

- treat underlying cause
- treatment goal is to return critical organ perfusion to normal (e.g. normalize BP)
- common treatment modalities include
  - fluid resuscitation
  - inotropes (e.g. dobutamine), vasopressors (e.g. norepinephrine), vasopressin
  - revascularization or thrombolytics for ischemic events

### Sepsis

- the leading cause of death in noncoronary ICU settings is multi-organ failure due to sepsis
- the predominant theory is that sepsis is attributable to uncontrollable immune system activation

**Definitions**

- sepsis: the presence of both infection and SIRS (see Table 36)
- severe sepsis: sepsis associated with organ dysfunction, hypoperfusion or hypotension
- septic shock: sepsis with arterial hypotension despite adequate fluid resuscitation
• multiorgan dysfunction syndrome: sepsis in the presence of altered organ function such that homeostasis cannot be maintained without intervention

Signs and Symptoms

</tbody>
</table>

Tissue Perfusion Variables

- Hyperlactatemia (>1 mmol/L)
- Decreased capillary refill or mottling

Treatment

- identify the cause and source of infection: blood, sputum, urine Gram stain, and C&S
- initiate empiric antibiotic therapy
- monitor, restore, and maintain hemodynamic function

Early Goal Directed Therapy

- adjustments of cardiac preload, afterload, and contractility to balance oxygen delivery with demand
- should be started immediately and completed within 6 h of recognition of severe sepsis or septic shock
- patient should meet SIRS criteria and sBP <90 mmHg or lactate >4 mmol/L
  1. supplemental oxygen ± intubation and mechanical ventilation
  2. central venous and arterial catheterization
  3. maintain CVP 8-12 mmHg with IV crystalloids/colloids
  4. MAP maintained 65-90 mmHg with the use of vasoactive agents
  5. Svo₂ <70% then
     - transfusion of red cells until Hct >30%
  - if Svo₂ <70% after transfusion then use inotropic agents
- supportive oxygenation and ventilation using lung-protective regimen
- early nutritional support: enteral route is used to preserve function of intestinal mucosal barrier
- control hyperglycemia with insulin to decrease infectious complications
- physiologic dose corticosteroid replacement therapy in patients with relative adrenal insufficiency (nonresponders to corticotropin stimulation test)
- consider in mechanically ventilated septic shock patients with organ dysfunction requiring vasopressors, despite early goal-directed therapy and appropriate antibiotic therapy
- recombinant activated protein C may be considered in patients with severe sepsis or septic shock with an APACHE II score >25 despite early goal-directed therapy and appropriate antibiotic therapy
- DVT/PE prophylaxis
- advanced care planning, including the communication of likely outcomes and realistic goals of treatment with patients and families

Corticosteroids for Treating Severe Sepsis and Septic Shock

Cochrane DB Syst Rev. 2010;CD002243

Study: Meta-analysis of 25 RCTs and quasi-RCTs examining the efficacy of corticosteroids on death at one month in patients with severe sepsis and septic shock.

Results: Overall, there was no difference in 28-d all-cause mortality but there was significant heterogeneity in dosing strategy between the studies. Treatment with long course of low dose corticosteroids significantly reduced 28-d mortality, increased the proportion of shock reversal by day 7 and day 28, reduced the sepsis-related organ failure assessment score by day 7, and survivors' length of stay in the ICU, without inducing gastrointestinal bleeding, superinfection, or neuromuscular weakness. Corticosteroids increased the risk of hyperglycemia and hypernatremia.

Conclusions: Corticosteroids did not change mortality in severe sepsis and septic shock. A long course of low dose corticosteroids reduced 28-d mortality without major complications.

Anatomy of Joint Pathology

- Normal Joint
- Degenerative Joint
- Inflammatory Joint

Basics of Immunology

Immunogenetics and Disease

- cell surface molecules called HLAAs play a role in mediating immune reactions
- MHC are genes on the short arm of chromosome 6 that encode HLA molecules
- certain HLA haplotypes are associated with increased susceptibility to autoimmune diseases

Terminology in Rheumatology

Arthritis
- Joint swelling: effusion/synovial thickening
- Decreased ROM
- Stress pain (pain at the end of ROM)
- Increased warmth

Arthralgia: perception of joint pain without obvious clinical findings

Active Joint: swollen joint, joint line tenderness, or stress pain

Innate Immune Cells
- Neutrophil (PMN): circulate in blood and respond to inflammatory stimuli, kill invading organisms by phagocytosis, degranulation and neutrophil extracellular traps
- Natural Killer Cell: innate immunity against intracellular infections (especially viruses), killing function and produce cytokines
- Macrophage: arrive after PMNs, suppress PMN efflux and phagocytose PMN debris, secrete pro-inflammatory cytokines in response to microbial debris
- Dendritic Cell: actively phagocytic when immature, activated by signals from toll-like receptor (TLR), release pro-inflammatory cytokines, present antigens to T cells in lymph nodes
- Cosinophil: respond to inflammatory cytokines and degranulate releasing reactive oxygen species, and cytokines, associated with allergy, asthma and parasitic infection
- Mast Cell: present in connective tissue and mucosa, allergen cross-linking of IgE bound to mast cell triggers degranulation and release of inflammatory mediators

Adaptive Immune Cells
- B Cell: produce antibodies after activation by specific antigen and B-cell co-receptor, additional signals provided by CD4 T helper cells
- Cytotoxic T Cell: CD8, direct cytotoxicity of target cells at sites of infection, kill via lytic granules and FasL-Fas interaction, recognize specific antigen and MHC1
- Helper T Cell: subset of CD4 cells, activate and help other types of cells carry out immune defense (activate macrophages, help B cells, release cytokines)
- Regulatory T Cell: Subset of CD4 cells, suppress activation of naive autoreactive T cells

Key Cytokine Targets of Biologic Drugs

TNF
- Source: T cells, macrophages
- Major Functions: cachexia, induces other cytokines, T cell stimulation, induces metalloproteinases and prostaglandins, increases expression of adhesion molecules, increases vascular permeability leading to increased entry of IgG, complement and cells into tissues

IL-6
- Source: Many cells
- Major Functions: proliferation of B and T cells, acute phase reactant, induces natural protease inhibitor

Common Investigations in Rheumatology
- general: CBC, electrolytes, Cr
- acute phase reactants: ESR, CRP, ferritin, albumin, fibrinogen, platelets
- complement (C3, C4)
- U/A to detect disease complications (proteinuria, active sediment)
- serology; see Table 10
- synovial fluid analysis
- radiology (plain film x-ray, CT, MRI, U/S, bone densitometry, angiography, bone scan)

Synovial Fluid Analysis
- synovial fluid is an ultrafiltrate of plasma plus hyaluronic acid; it lubricates joint surfaces and nourishes articular cartilage

Indications
- diagnostic: mandatory if septic arthritis suspected; advised if crystal arthritis or hemarthrosis suspected; advised if unexplained effusion in accessible joint
- therapeutic: drainage of blood, purulent or tense effusions; corticosteroid injection

Contraindications
- absolute: open lesion or suspected infection of overlying skin or soft tissue
- relative: bleeding diathesis, thrombocytopenia, prosthetic joint

Synovial Fluid Analysis
- ensure synovial fluid is described in terms of colour, clarity, viscosity, and quantity
- culture and gram stain (bacteria, mycobacteria, fungi)
- if only have 1 mL of fluid, prioritize culture and gram stain
- cell count and differential
- crystal examination (microscopy with polarized light)
  - gout (monosodium urate) → needle-shaped, negatively birefringent (bright yellow)
  - pseudogout (CPPD) → rhomboid-shaped, positively birefringent (pale blue)

Table 8. Synovial Fluid Analysis

Choosing Wisely Canada
Recommendations
1. Do not order ANA as a screening test in patients without specific signs or symptoms of SLE or another CTD
2. Do not order an HLA-B27 unless spondyloarthritis is suspected based on specific signs or symptoms
3. Do not repeat DEXA scans more often than every 2 years
4. Do not prescribe bisphosphonates for patients at low risk of fracture
5. Do not perform whole body bone scans (e.g. scintigraphy) for diagnostic screening for peripheral and axial arthritis in the adult population

Septic Arthritis
- for any acute monoarthritis or flare of pre-existing arthritis, one must rule out septic etiology; consider empiric antibiotic treatment until septic arthritis is excluded by history, physical exam, and synovial fluid analysis
- major bacteria are gram positive cocci (75-80%) especially S. aureus, and gram-negative bacilli (15-20%)
- poor prognostic factors: older age, immunocompromised, delay in treatment, previously damaged joint, joint prosthesis
- see Infectious Diseases for Gonococcal Arthritis, ID15 and Orthopedics, OR10

Septic arthritis is a medical emergency; it leads to rapid joint destruction, and there is a 10-15% risk of mortality
**Degenerative Arthritis: Osteoarthritis**

**Definition**
- progressive deterioration of articular cartilage and surrounding joint structures caused by genetic, metabolic, biochemical, and biomechanical factors with secondary components of inflammation

**Classification (based on etiology)**
- primary (idiopathic)
  - most common, unknown etiology
- secondary
  - post-traumatic or mechanical
  - post-inflammatory (e.g. RA) or post-infectious
  - heritable skeletal disorders (e.g. scoliosis)
  - endocrine disorders (e.g. acromegaly, hyperparathyroidism, hypothyroidism)
  - metabolic disorders (e.g. gout, pseudogout, hemochromatosis, Wilson’s disease, ochronosis)
  - neuropathic (e.g. Charcot joints)
  - atypical joint trauma due to peripheral neuropathy (e.g. DM, syphilis)
  - AVN
  - other (e.g. congenital malformation)

**Pathophysiology**
- the process appears to be initiated by abnormalities in biomechanical forces and/or, less often, in cartilage
- elevated production of pro-inflammatory cytokines is important in OA progression
- tissue catabolism > repair
- genetic, environmental, mechanical loading, age and gender factors contribute, but mechanism is unknown
- now considered to be a systemic musculoskeletal disorder rather than a focal disorder of synovial joints

**Epidemiology**
- most common arthropathy (accounts for ~75% of all arthritis)
- increased prevalence with increasing age (35% of 30 yr olds, 85% of 80 yr olds)

**Risk Factors**
- genetic predisposition, advanced age, obesity (for knee and hand OA), female, trauma

**Signs and Symptoms**
- localized to affected joints (not a systemic disease)
- pain is often insidious, gradually progressive, with intermittent flares and remissions, neuropathic pain may also be present
- fatigue, poor sleep, impact on mood (depression, anxiety)

<table>
<thead>
<tr>
<th>Signs</th>
<th>Symptoms</th>

</tr>
<tr>
<td>Inflammation (mild if present)</td>
<td>*</td>
</tr>
<tr>
<td>Patiarticular muscle atrophy</td>
<td>*</td>
</tr>
</tbody>
</table>

**Joint Involvement**
- asymmetric (knees usually affected bilaterally)
- hand
  - DIP (Heberden’s nodes = osteophytes → enlargement of joints)
  - PIP (Bouchard’s nodes)
  - CMC (usually thumb squaring)
  - 1st MCP (other MCPs are usually spared)
- hip
  - usually presents as groin pain ± dull or sharp pain in the trochanteric area, internal rotation and abduction are lost first
  - pain can radiate to the anterior thigh, but generally does not go below the knee
- knee
  - initial narrowing of one compartment, medial > lateral; seen on standing x-rays, often patellar-femoral joint involved

**The Radiographic Hallmarks of OA**
- Joint space narrowing
- Subchondral sclerosis
- Subchondral cysts
- Osteophytes

**Obesity is linked to OA in the knee as well as CMC, which suggests a systemic inflammatory component to OA**

**Figure 3. Common sites of joint involvement in OA**
- Hand (DIP, PIP, 1st CMC)
- Hip
- Knee
- 1st MTP
- L-spine (L4-L5, L5-S1)
- C-spine
- Uncommon: ankle, shoulder, elbow, MCP, rest of wrist

**Figure 4. Hand findings in OA**
- OA of MCP joints can be seen in hemochromatosis or chondrocalcinosis
• foot
  - common in first MTP and midfoot
• lumbar spine
  - very common, especially L4-L5, L5-S1
  - degeneration of intervertebral discs and facet joints
• reactive bone growth can contribute to neurological impingement (e.g. sciatica, neurogenic claudication) or spondylolisthesis (forward or backward movement of one vertebra over another)
• cervical spine
  - commonly presents with neck pain that radiates to scapula, especially in mid-lower cervical area (C5 and C6)

Investigations
• blood work
  - normal CBC and ESR, CRP
  - negative RF and ANA
• radiology: 4 hallmark findings
• synovial fluid: non-inflammatory (see Table 8)

Treatment
• presently no treatment alters the natural history of OA
• prevention: prevent sports injury, healthy weight management
• non-pharmacological therapy
  - weight loss (minimum 5-10 lb loss) if overweight
  - physiotherapy: heat/cold, low impact exercise programs
  - occupational therapy: aids, splints, cane, walker, bracing
• pharmacological therapy (see Table 32)
  - oral: acetaminophen/NSAIDs, glucosamine ± chondroitin (nutraceuticals not proven)
  - treat neuropathic pain if present (anti-depressants, anti-epileptics, etc.)
  - joint injections: corticosteroid, hyaluronic acid (questionable benefit)
  - topical: capsaicin, NSAIDs
• surgical treatment
  - joint debridement, osteotomy, total and/or partial joint replacement, fusion
    (see Orthopedics, OR30)

Seropositive Rheumatic Disease
• diagnosis vs. classification in rheumatology
• diagnostic criteria are often dependent on disease progression and evolution over time, as early objective measures are often unavailable
• classification criteria are derived from studying patients with long-term diseases and clear diagnoses in order to determine which criteria have good specificity in the early prediction of certain diagnoses
• seropositive arthropathies are characterized by the presence of a serologic marker such as positive RF or ANA
• a small subset of the vasculitides, the small vessel ANCA-associated vasculitides, have a measurable serological component, but even these are often considered a separate entity from seropositive disease by experts

RA is an independent risk factor for atherosclerosis and CV disease. RA is associated with increased overall mortality/morbidity from all causes: CV disease, neoplasm (especially lymphoma), infection.

**Common Presentation**
- Morning stiffness >1 h, improves with use
- Symmetric joint involvement
- Initially involves small joints of hands and feet
- Constitutional symptoms
Pathophysiology

- autoimmune disorder, unknown etiology
- complex interaction of genes and environment leading to breakdown of immune tolerance: many pathways result in autoreactivity leading to a final common pathway to synovial inflammation
  - genetic predisposition: HLA-DR4/DR1 association (93% of patients have either HLA type), cytokine promotors, T cell signaling
  - epigenetic: DNA hypomethylation, dysregulated histones, microRNA expression
  - environment: repeated activation of innate immunity, cigarette smoking increases susceptibility 20-40 fold
    - induction of enzymes that convert arginine to citrulline caused by environmental stress (cigarette smoking)
  - RA: propensity for immune reactivity to neoepitopes created by protein citrullination and production of anti-citrullinated protein antibodies
  - second-hit required for autoantibody-mediated synovial inflammation: increase in vascular permeability provides access to joint and permits complement fixation, recruitment of immune cells, and inflammation
- once inflammatory process is established, synovium organizes itself into an invasive tissue that degrades cartilage and bone
  - direct invasion of proliferating synovial fibroblast cells into cartilage at the pannus-cartilage junction; inflammatory mediators lead to release of collagenases resulting in destruction of articular cartilage and subchondral bone
  - fibroblast-like synoviocytes in the rheumatoid synovium can migrate from joint to joint (may explain symmetric polyarticular presentation)
- progressive bone destruction with absence of bone repair in response to inflammation
  - TNF increases osteoclasts and decreases osteoblasts at the site of inflammation
  - RANK ligand regulates osteoclast-mediated destruction

Epidemiology

- most common inflammatory arthritis: prevalence 1% of population
- F:M = 3:1
- age of onset 20-40 yr

Signs and Symptoms

- variable course of exacerbations and remissions
- morning stiffness >1 h, improves with use, increases with rest
- polyarthritis: symmetric joint involvement (tender, swollen), small joints affected, most commonly MCP, PIP, MTP
- extra-articular (systemic) symptoms: profound fatigue, depression, myalgia, weight loss
- limitation of function and decrease in global functional status
- complications of chronic synovitis
  - signs of mechanical joint damage: loss of motion, instability, deformity, crepitus, joint deformities
    - swan neck deformity, boutonnière deformity
    - ulnar deviation of MCP, radial deviation of wrist joint
    - hammer toe, mallet toe, claw toe
    - flexion contractures
  - atlanto-axial and subaxial subluxation
  - C-spine instability
  - neurological impingement (long tract signs)
  - difficult/dangerous intubation: risk of worsening subluxation and damage to spinal cord
  - limited shoulder mobility, spontaneous tears of the rotator cuff leading to chronic spasm
  - tenosynovitis → may cause rupture of tendons
  - carpal tunnel syndrome
  - ruptured Baker’s cyst (outpouching of synovium behind the knee); presentation similar to acute DVT

Figure 5. Common sites of joint involvement in RA

Figure 6. Joint deformities

Syndromes in RA
- SS (common): keratoconjunctivitis sicca and xerostomia (dry eyes and mouth)
- Caplan’s syndrome (rare): multiple pulmonary nodules and pneumoconiosis
- Felty’s syndrome (rare): arthritis, splenomegaly, neutropenia
Classification of Global Functional Status in RA

- **Class I**: able to perform usual ADLs (self-care, vocational, avocational)
- **Class II**: able to perform self-care and vocational activities, restriction of avocational activities
- **Class III**: able to perform self-care, restriction of vocational and avocational activities
- **Class IV**: limited ability to perform self-care, vocational, and avocational activities

Investigations

- blood work
  - RF: sensitivity 80% but non-specific; may not be present at onset of symptoms; levels correlate with disease activity
  - can be associated with more erosions, more extra-articular manifestations, and worse function
  - anti-CCP: sensitivity 80% but more specific (94-98%); may precede onset of symptoms
  - increased disease activity is associated with decreased Hb (anemia of chronic disease), increased platelets, ESR, CRP, and RF
- imaging
  - x-rays may be normal at onset
  - first change is periarticular osteopenia, followed by erosions
  - U/S, MRI may be used to image hands to detect early synovitis and erosions

Treatment

- goals of therapy: remission or lowest possible disease activity
- control disease activity
- relieve pain and stiffness
- maintain function and lifestyle
- prevent or control joint damage
- key is early diagnosis and early intervention with DMARDs
- “window of opportunity” = early treatment within first 3 mo of disease may allow better control/remission
- behavioural
  - exercise program (isometrics and active, gentle ROM exercise during flares, aquatic/aerobic/strengthening exercise between flares), assistive devices as needed
- job modification may be necessary
- pharmacologic: alter disease progression
  - DMARDs
    - Standard of care and should be started as soon as possible
    - MTX is the gold standard and is first-line unless contraindicated
      - delayed onset of action (may take 8-12 wks)
      - potential toxicities: GI, hematologic, hepatic, pulmonary, teratogenic
      - if inadequate response (3-6 mo) → combine or switch
      - add-ons include: hydroxychloroquine, sulfasalazine, leflunomide
  - biologics
    - indicated if inadequate response to DMARDs
    - can be combined with DMARD therapy
    - options: infliximab, etanercept, adalimumab, abatacept, rituximab, tocilizumab
    - reassess every 3-6 mo and monitor disease severity
- pharmacologic: reduce inflammation and pain
  - NSAIDs
    - individualize according to efficacy and tolerability
    - contraindicated/cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy)
    - add acetaminophen ± opioid prn for synergistic pain control
  - corticosteroids
    - local: injections to control symptoms in a specific joint
    - systemic (prednisone)
      - low dose (5-10 mg/d) useful for short-term to improve symptoms if NSAIDs ineffective, to bridge gap until DMARDs take effect
      - severe RA: add low dose prednisone to DMARDs
      - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy if using corticosteroids >3 mo at 7.5mg/d
      - cautions/contraindications: active infection, TB, osteoporosis, HTN, gastric ulcer, DM

Follow-Up Management and Clinical Outcomes

- follow-up every 3-6 mo, then 6-12 mo after inflammation has been suppressed
- examine joints for active inflammation – if active, consider adjusting medications, PT/OT
- if assessment reveals joint damage – consider analgesia, referral to PT/OT, surgical options
- outcome depends on disease activity, joint damage, physical functional status, psychological health, and comorbidities

Conclusions

- Initial combination therapy with prednisone or infliximab results in faster response rates. Whether faster initial response rates leads to better long-term disease outcomes has not yet been studied.

Comparison of Treatment Strategies in Early Rheumatoid Arthritis

- **Rheumatoid Arthritis**
- **Classification of Global Functional Status in RA**
- **Investigations**
- **Treatment**
- **Follow-Up Management and Clinical Outcomes**
- **Conclusions**

- Poor prognostic features of RA include: young age of onset, high RF titer, elevated ESR, activity of >20 joints, and presence of extra-articular features

- Only DMARDs and biologics (not analgesics or NSAIDs) after the course of RA

- Standard of care and should be started as soon as possible

- **Side Effects of Steroids**
  - Weight gain
  - Osteoporosis
  - AVN
  - Cataracts, glaucoma
  - PUD
  - Susceptibility to infection
  - Easy bruising
  - Acne
  - HTN
  - Hyperlipidemia
  - Hypokalemia, hyperglycemia
  - Mood swings

  - Easy bruising
  - Acne
  - HTN
  - Hyperlipidemia
  - Hypokalemia, hyperglycemia
  - Mood swings

- Only DMARDs and biologics (not analgesics or NSAIDs) after the course of RA
• functional capacity is a useful tool for determining therapeutic effectiveness: many tools for evaluation have been validated
• patients with RA have an increased prevalence of other serious illnesses: infection (e.g. pulmonary, skin, joint), renal impairment, lymphoproliferative disorders, cardiovascular disease (correlates with disease activity and duration)
• increased risk of premature mortality, decreased life expectancy (most mortality not directly caused by RA)

Surgical Therapy
• indicated for structural joint damage
• surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Systemic Lupus Erythematosus

• see Nephrology, NP22 and Dermatology, D41

Definition
• chronic inflammatory multi-system disease of unknown etiology
• characterized by production of autoantibodies and diverse clinical manifestations

Table 14. Diagnostic Criteria of SLE*

<td>ANA Most sensitive test (98%), not specific</td>
</tr>
</tbody>
</table>

*Note: “4, 7, 11” rule → 4 (or more) out of 11 criteria (4 lab, 7 clinical) must be present, serially or simultaneously, for diagnosis

Etiology and Pathophysiology
• production of autoantibodies causing multi-organ inflammation
• multi-factorial etiology
• genetics
  • common association with HLA-B8/DR3: ~10% have positive family history
  • strong association with defects in apoptotic clearance → fragments of nuclear particles captured by antigen-presenting cells → develop anti-nuclear antibodies
  • cytokines involved in inflammatory process and tissue injury: B-lymphocyte stimulator (BlyS), IL-6, IL-17, IL-18, TNF-α
• environment
  • UV radiation, cigarette smoking, infection, vitamin D deficiency
  • estrogen
  • increased incidence after puberty, decreased incidence after menopause
  • men with SLE have higher concentration of estrogenic metabolites
• infection
  • viral (non-specific stimulant of immune response)
• drug-induced
  • anti-hypertensives (hydralazine), anti-convulsants (phenytoin), anti-arrhythmics (propranolol), isoniazid, biologics, oral contraceptive pills
  • anti-histone Ab are commonly seen in drug-induced SLE
  • symptoms resolve with discontinuation of offending drug
Epidemiology
- prevalence: 0.05% overall
- F:M = 10:1
- age of onset in reproductive yr (13-40)
- more common and severe in African-Americans and Asians
- bimodal mortality pattern
  - early (within 2 yr)
    - active SLE, active nephritis, infection secondary to steroid use
  - late (>10 yr)
    - inactive SLE, inactive nephritis, atherosclerosis likely due to chronic inflammation

Signs and Symptoms
- characterized by periods of exacerbation and remission

Table 15. Symptoms of SLE

<td>Respiratory: pulmonary hypertension, pulmonary hemorrhage, emboli</td>
</tr>
</tbody>
</table>

Investigations
- ANA (sensitivity 98%, but poor specificity → used as a screening test, ANA titres are not useful to follow disease course)
- anti-dsDNA and anti-Sm are specific (95-99%)
- anti-dsDNA titer and serum complement (C3, C4) are useful to monitor treatment response in patients who are clinically and serologically concordant
  - anti-dsDNA increases and C3 and C4 decrease with disease activity
- antiphospholipid Ab (anti-cardiolipin Ab and SLE anticoagulant), may cause increased risk of clotting and increased aPTT

Treatment
- goals of therapy
  - treat early and avoid long-term steroid use, if unavoidable see Endocrinology, E42 for osteoporosis management
  - if high doses of steroids necessary for long-term control, add steroid-sparing agents and taper when possible
  - treatment is tailored to organ system involved and severity of disease
  - all medications used to treat SLE require periodic monitoring for potential toxicity
- dermatologic
  - sunscreen, avoid UV light and estrogens
  - topical steroids, hydroxychloroquine
- musculoskeletal
  - NSAIDs ± gastroprotective agent for arthritis (also beneficial for pleuritis and pericarditis)
  - hydroxychloroquine improves long-term control and prevents flares
  - bisphosphonates, calcium, vitamin D to combat osteoporosis
- organ-threatening disease
  - high-dose oral prednisone or IV methylprednisolone in severe disease
  - steroid-sparing agents: azathioprine, MTX, mycophenolate mofetil
  - IV cyclophosphamide for serious organ involvement (e.g. cerebritis or lupus nephritis) see Nephrology, NP22 for clinical features of lupus nephritis

Drug-Induced SLE
Often presents atypically with systemic features and serositis; usually associated with anti-histone Ab

Raynaud’s Phenomenon
Vasospastic disorder characteristically causing discoloration of fingers and toes (white → blue → red). Classic triggers: cold and emotional stress

Radiographically, the arthritis of SLE is non-erosive (unlike RA)

Consider SLE in a patient who has involvement of 2 or more organ systems
Antiphospholipid Antibody Syndrome

Definition
- multi-system vasculopathy manifested by recurrent thromboembolic events, spontaneous abortions, and thrombocytopenia
- often presents with migraine-type H/As
- circulating antiphospholipid autoantibodies interfere with coagulation cascade
- primary APLA: occurs in the absence of other disease
- secondary APLA: occurs in the setting of a connective tissue disease (including SLE), malignancy, drugs (hydralazine, procainamide, phenytoin, interferon, quinidine), and infections (HIV, TB, hepatitis C, infectious mononucleosis)
- catastrophic APLA: development within 1 wk of small vessel thrombotic occlusion in ≥3 organ systems with positive antiphospholipid Ab (high mortality)

Table 16. Classification Criteria of APLA*

- see clinical criteria in Table 16
- hematologic
  - thrombocytopenia, hemolytic anemia, neutropenia
- dermatologic
  - livedo reticularis, Raynaud's phenomenon, purpura, leg ulcers, and gangrene

Treatment
- thrombosis
  - lifelong anti-coagulation with warfarin
  - target INR 2.0-3.0 for first venous event, >3.0 for recurrent and/or arterial event
- recurrent fetal loss
  - heparin/low molecular weight heparin ± ASA during pregnancy
- catastrophic APLA
  - high-dose steroids, anti-coagulation, cyclophosphamide, plasmapheresis

Scleroderma (i.e. Systemic Sclerosis)

Definition
- a non-inflammatory autoimmune disorder characterized by widespread small vessel vasculopathy, production of autoantibodies, and fibroblast dysfunction causing fibrosis

Figure 8. Forms of scleroderma

* Score of ≥9 is sufficient to classify a patient as having definite scleroderma (sensitivity 0.95, specificity 0.93)  
Arthritis & Rheum 2013;65(11):2737-2747  

Etiology and Pathophysiology  
• idiopathic vasculopathy (not vasculitis) leading to atrophy and fibrosis of tissues  
  • intimal proliferation and media mucinous degeneration → progressive obliteration of vessel lumen → fibrotic tissue  
  • resembles malignant HTN  

Epidemiology  
• F:M = 3-4:1, peaking in 5th and 6th decades  
• associated with HLA-DR1  
• associated with environmental exposure (silica, epoxy resins, toxic oil, aromatic hydrocarbons, polyvinyl chloride)  
• limited systemic sclerosis has a higher survival prognosis (>70% at 10 yr) than diffuse systemic sclerosis (40-60% at 10 yr)  

Signs and Symptoms  
Table 18. Clinical Manifestations of Scleroderma  

<table>
<thead>
<tr>
<th>System</th>
<th>Features</th>
</tr>
</thead>
</table>
| Dermatologic | Painless non-pitting edema → skin tightening  
Ulcations, calcinosis, periungual erythema, hypo/hyperpigmentation, pruritus, telangiectasias  
Characteristic face: mask-like facies with tight lips, beak nose, radial perioral furrows |
| Vascular | Raynaud’s phenomenon → digital pust, gangrene |
| Gastrointestinal (~90%) | Distal esophageal hypomotility → dysphagia  
Loss of lower esophageal sphincter function → GERD, ulcerations, strictures  
Small bowel hypomotility → bacterial overgrowth, diarrhea, bloating, cramps, malabsorption, weight loss  
Large bowel hypomotility → wide mouth diverticuli are pathognomonic radiographic finding on barium study |
| Renal | Mild proteinuria, Cr elevation, HTN  
“Scleroderma renal crisis” (10-15%) may lead to malignant arterial HTN, oliguria, and microangiopathic hemolytic anemia |
| Pulmonary | Interstitial fibrosis, pulmonary HTN, pleurisy, pleural effusions |
| Cardiac | Left ventricular dysfunction, pericarditis, pericardial effusion, arrhythmias |
| Musculoskeletal | Polyarthritis  
“Resorption of distal tufts” (radiological finding)  
Proximal weakness 2° to disuse, atrophy, low grade myopathy |
| Endocrine | Hypothyroidism |

Investigations  
• blood work  
  • CBC, Cr, ANA  
  • anti-topoisomerase 1/anti-Scl-70: specific but not sensitive for diffuse systemic sclerosis  
  • anti-centromere: favours diagnosis of CREST (limited systemic sclerosis)  
• PFT  
  • assess for interstitial lung disease  
• imaging  
  • CXR for fibrosis, echo for pulmonary HTN  

Scleroderma is the most common cause of secondary Raynaud’s phenomenon  
Lung disease is the most common cause of morbidity and mortality  
Raynaud’s Phenomenon DDx  
COLD HAND  
Cryoglobulins/Cryofibrinogens  
Obstruction/Occupational  
Lupus erythematosus, other connective tissue disease  
Diabetes mellitus/Drugs  
Hematologic problems (polycythemia, leukemia, etc.)  
Arterial problems (atherosclerosis)/  
Anorexia nervosa  
Neurologic problems (vascular tone)  
Disease of unknown origin (idiopathic)  
Features of Pathologic Raynaud’s Syndrome  
• New onset  
• Asymmetric  
• Precipitated by stimuli other than cold or emotion  
• Associated with distal pulp pitting or tissue reabsorption  
• Digit ischemia  
• Capillary dilatation by capillaroscopy
**Treatment**

- **dermatologic**
  - good skin hygiene
  - low-dose prednisone (>20 mg may provoke renal crisis if susceptible), MTX (limited evidence)
- **vascular**
  - patient education on cold avoidance
  - vasodilators (CCBs, local nitroglycerine cream, systemic PGE₂ inhibitors, PDE5 inhibitors)
- **gastrointestinal**
  - GERD: PPIs are first line, then H₂-receptor agonists
  - small bowel bacterial overgrowth: broad spectrum antibiotics (tetracycline, metronidazole)
- **renal disease**
  - ACEI for hypertensive crisis
  - see Nephrology, NP31 for scleroderma renal crisis
- **pulmonary**
  - early interstitial disease: cyclophosphamide
  - pulmonary HTN: vasodilators e.g. bosentan (Tracleer®), epoprostenol (Flolan®), PDE5 inhibitors
- **cardiac**
  - pericarditis: systemic steroids
- **musculoskeletal**
  - arthritis: NSAIDs
  - myositis: systemic steroids

---

**Idiopathic Inflammatory Myopathy**

**Definition**

- autoimmune diseases characterized by proximal muscle weakness = pain
- muscle becomes damaged by a non-suppurative lymphocytic inflammatory process

**Classification**

- **PM/DMM**
  - adult and juvenile form
  - associated with malignancy
    - increased risk of malignancy: age >50, DMM>PM, normal CK, refractory disease
    - 2.4-6.5 fold increased risk of underlying malignancy usually in internal organs
  - associated with other connective tissue disease, Raynaud’s phenomenon, autoimmune disorders

**Inclusion Body Myositis**

- age >50, M>F, slowly progressive, vacuoles in cells on biopsy
- suspect when patient unresponsive to treatment
- distal as well as proximal muscle weakness
- muscle biopsy positive for inclusion bodies

**POLYMYOSITIS/DERMATOMYOSITIS**

**Table 19. Classification Criteria for PM/DMM**

NEJM 1975;292:403-407

**Etiology and Pathophysiology**

- PM is CD8 cell-mediated muscle necrosis, found in adults
- DMM is B-cell and CD4 immune complex-mediated peri-fascicular vascular abnormalities

**Signs and Symptoms**

- progressive symmetrical proximal muscle weakness (shoulder and hip) developing over weeks to months
  - difficulty lifting head off pillow, arising from chair, climbing stairs
- dermatological
  - DMM has characteristic dermatological features (F>M, children and adults)
    - Gottron’s papules
      - pink-violaceous, flat-topped papules overlying the dorsal surface of the interphalangeal joints
    - Gottron’s sign

Signs of DMM
Gottron’s papules and Gottron’s sign are pathognomonic of DMM (occur in 70% of patients)

---

Malignancies Associated with DMM
- Breast
- Lung
- Colon
- Ovarian
• Gottron’s sign
  – erythematous, smooth or scaly patches over the dorsal IPs, MCPs, elbows, knees, or medial malleoli
• heliotrope rash: violaceous rash over the eyelids; usually with edema
• shawl sign: poikilodermatous erythematous rash over neck, upper chest, and shoulders
• mechanic’s hands: dark, dry, thick scale on palmar and lateral surface of digits
• periungual erythema

• cardiac
  – arrhythmias, CHF, conduction defect, ventricular hypertrophy, pericarditis
• gastrointestinal
  – oropharyngeal and lower esophageal dysphagia, reflux
• pulmonary
  – weakness of respiratory muscles, ILD, aspiration pneumonia

Investigations
• blood work: CK, ANA, anti-Jo-1 (DMM), anti-Mi-2, anti-SRP
• imaging: MRI may be used to localize biopsy site
• EMG, muscle biopsy

Treatment
• non-pharmacological treatment
  – physical therapy and occupational therapy
• pharmacological treatment
  – high-dose corticosteroid (1-2 mg/kg/d) and slow taper
  – add immunosuppressive agents (azathioprine, MTX, cyclosporine)
  – IVIg if severe or refractory
  – hydroxychloroquine for DMM rash
• malignancy surveillance
  – detailed history and physical (breast, pelvic, and rectal exam)
  – CXR, abdominal and pelvic U/S, fecal occult blood, Pap test, mammogram ± CT scan (thoracic, abdominal, pelvic)

Sjögren’s Syndrome

Definition
• autoimmune condition characterized by dry eyes (keratoconjunctivitis sicca/xerophthalmia) and dry mouth (xerostomia), caused by lymphocytic infiltration of salivary and lacrimal glands
• may evolve into systemic disorder with diminished exocrine gland activity in respiratory tract and skin
• primary and secondary form (associated with RA, SLE, DMM, and HIV)
• incidence estimated at 4/100,000 people
• 90% of cases are among females
• mean age of diagnosis is 40-60 yr

Table 20. American College of Rheumatology Classification for Sjögren’s*

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Positive serum anti-SSA/Ro and/or anti-SSB/</td>
<td>La gr positive RF and ANA titer&gt;1:320</td>
</tr>
<tr>
<td>2. Labial salivary gland biopsy with focal lymphocytic sialadenitis with focus score ≥1 focus 4/mm²</td>
<td>Focus scores are histopathologic grading systems</td>
</tr>
<tr>
<td>3. Keratoconjunctivitis sicca with ocular staining score &gt;3</td>
<td>Orificial staining score based on fluorescein dye examination of conjunctiva and cornea to determine clinical changes</td>
</tr>
</tbody>
</table>

*Sjögren’s criteria is met in patients with signs/symptoms of Sjögren’s, who have at least 2 of the above features

Signs and Symptoms
• “sicca complex”: dry eyes (keratoconjunctivitis sicca/xerophthalmia), dry mouth (xerostomia)
• staphylococcal blepharitis
• dental caries, oral candidiasis, angular cheilitis (inflammation and fissuring at the labial commissures of the mouth)
• systemic complications
  – sinustis
  – autoimmune thyroid dysfunction
  – arthralgias, arthritis
  – subclinical diffuse ILD, xerotrachea leading to chronic dry cough
  – renal disease, glomerulonephritis
  – palpable purpura, vasculitis
  – peripheral neuropathy
• lymphoma risk greatly increased

Treatment
• ocular
  – artificial tears or surgical punctal occlusion for dry eyes
• oral
  - good dental hygiene, hydration
  - parasympathomimetic agents that stimulate salivary flow (e.g. pilocarpine)
  - topical nystatin or clotrimazole x 4-6 wk for oral candidiasis
• systemic
  - e.g. hydroxychloroquine, corticosteroids

**Mixed Connective Tissue Disease**

• syndrome with features of 3 different connective tissue diseases (e.g. SLE, scleroderma, PM)
• common symptoms: Raynaud’s phenomenon, swollen fingers
• blood work: anti-RNP (see Table 10)
• treatment is generally guided by the severity of symptoms and organ system involvement
• prognosis
  - 50-60% will evolve into SLE
  - 40% will evolve into scleroderma
  - only 10% will remain as MCTD for the rest of their lives
  - cardiac involvement (arrhythmia) common, renal or lung involvement rare

**Overlap Syndrome**

• syndrome with sufficient diagnostic features of 2+ different connective tissue diseases

**Vasculitides**

• inflammation and subsequent necrosis of blood vessels leading to tissue ischemia or infarction
• any organ system can be involved
• keys to diagnosis
  - clinical suspicion: suspect in cases of unexplained multiple organ ischemia or systemic illness with no evidence of malignancy or infection
  - labs non-specific: anemia, increased WBC and ESR, abnormal U/A
  - biopsy if tissue accessible
  - angiography if tissue inaccessible
• treatment generally involves corticosteroids and/or immunosuppressive agents

Figure 9. Classification of vasculitides by vessel size

Small Vessel Non-ANCA Associated Vasculitis

CUTANEOUS VASCULITIS
- subdivided into
  - drug-induced vasculitis
  - serum sickness reaction
  - vasculitis associated with other underlying primary diseases

Etiology and Pathophysiology
- cutaneous vasculitis following
  - drug exposure (allopurinol, gold, sulfonamides, penicillin, phenytoin)
  - viral or bacterial infection
  - idiopathic causes
- small vessels involved (post-capillary venules most frequently)
- usually causes a leukocytoclastic vasculitis: debris from neutrophils around vessels
- sometimes due to cryoglobulins which precipitate in cold temperatures

Signs and Symptoms
- palpable purpura ± vesicles and ulceration, urticaria, macules, papules, bullae, subcutaneous nodules
- renal or joint involvement may occur, especially in children

Investigations
- vascular involvement (both arteriole and venule) established by skin biopsy

Treatment
- stop possible offending drug
- corticosteroids ± immunosuppressive agents
- usually self-limiting
Small Vessel ANCA-Associated Vasculitis

GRANULOMATOSIS WITH POLYANGIITIS
(GPA, formerly known as Wegener’s Granulomatosis)

Definition
• granulomatous inflammation of vessels that may affect the upper airways (rhinitis, sinusitis), lungs (pulmonary nodules, infiltrates), and kidneys (glomerulonephritis, renal failure)
• highly associated with c-ANCA
• incidence 5 per 100,000; more common in Northern latitudes

<td>Lungs show granulomas, kidneys show necrotizing segmental glomerulonephritis</td>
</tr>
</tbody>
</table>

*Diagnosed if 2 or more of the above 4 criteria present American College of Rheumatology, 1990

Etiology
• pathogenesis depends on genetic susceptibility and environmental triggers (e.g. infection)
  ▪ dysregulated immune response due to loss of B and T-cell tolerance
  ▪ acute vascular injury mediated by neutrophils and monocytes

Signs and Symptoms
• systemic
  ▪ malaise, fever, weakness, weight loss
• HEENT
  ▪ sinusitis or rhinitis, nasal crusting and bloody nasal discharge, nasoseptal perforation, saddle nose deformity
  ▪ proptosis due to: inflammation/vasculitis involving extra-ocular muscles, granulomatous retroorbital space occupying lesions or direct extension of masses from the upper respiratory tract
  ▪ hearing loss due to involvement of CN VIII
• pulmonary
  ▪ cough, hemoptysis, granulomatous upper respiratory tract masses
• renal
  ▪ hematuria
• other
  ▪ joint, skin, eye complaints, vasculitic neuropathy

Investigations
• blood work: anemia (normal MCV), increased WBC, increased Cr, increased ESR, elevated platelet count, ANCA (PR3 > MPO)
• urinalysis: proteinuria, hematuria, RBC casts
• CXR: pneumonitis, lung nodules, infiltrations, cavitary lesions
• biopsy: renal (segmental necrotizing glomerulonephritis), lung (granulomas, tracheobronchial erosion)
• c-ANCA and ESR often correlate with disease activity and used to monitor response to treatment in some patients

Treatment
• prednisone 1 mg/kg/d PO ± cyclophosphamide 2 mg/kg/d PO for 3-6 mo followed by high dose MTX (20-25 mg PO/SC weekly) or azathioprine (2 mg/kg/d PO OD)
• consider biologic agents (rituximab, IVIg) and plasmapheresis (PEXIVAS trial)

Medium Vessel Vasculitis

POLYARTERITIS NODOSA

Definition
• systemic, necrotizing vasculitis of medium sized vessels
• ANCA negative
• 30% associated with hepatitis B positivity
• incidence 0.7 per 100,000; affects individuals between 40-60 yr; M:F = 2:1
Table 23. Classification Criteria for PAN*

<td>Presence of granulocytes and/or mononuclear leukocytes in the artery wall</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 10 criteria present  
American College of Rheumatology, 1990

**Etiology and Pathophysiology**
- focal panmural necrotizing inflammatory lesions in small and medium-sized arteries
- thrombosis, aneurysm, or dilatation at lesion site may occur
- healed lesions show proliferation of fibrous tissue and endothelial cells that may lead to luminal occlusion

**Investigations**
- blood work: CBC, ESR, Cr, BUN, p-ANCA, hepatitis B serology
- imaging: angiography
- arterial biopsy

**Treatment**
- prednisone 1 mg/kg/d PO and cyclophosphamide 2 mg/kg/d PO
- ± anti-viral therapy to enhance clearance of hepatitis B virus

### Large Vessel Vasculitis
- see Ophthalmology, OP38

**GCA/TEMPORAL ARTERITIS**

<tr>
<td>5. Abnormal artery biopsy</td>
<td>Mononuclear cell infiltration or granulomatous inflammation, usually with multinucleated giant cells</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 5 criteria present  
American College of Rheumatology, 1990

**Epidemiology**
- most frequent vasculitis in North America
- patients >50 yr
- F:M = 2:1
- North-South gradient (predominance in Northern Europe/US)
- affects extracranial arteries

**Signs and Symptoms**
- new onset temporal H/A ± scalp tenderness due to inflammation of involved portion of the temporal or occipital arteries
- sudden, painless loss of vision and/or diplopia due to narrowing of the ophthalmic or posterior ciliary arteries (PCA more common); can affect both eyes
- tongue and jaw claudication (pain in muscles of mastication on prolonged chewing)
- PMR (proximal myalgia, constitutional symptoms, elevated ESR) occurs in 30% of patients
- aortic arch syndrome (involvement of subclavian and brachial branches of aorta resulting in pulseless disease), aortic aneurysm ± rupture are late complications

**Medical Emergency**
Untreated, GCA can lead to permanent blindness in 20-25% of patients
Treat on clinical suspicion
Investigations
- diagnosis made by clinical suspicion, increased ESR, increased CRP, temporal artery biopsy within 14 d of starting steroids, possible U/S

Treatment
- if suspect GCA, immediately start high dose prednisone 1 mg/kg in divided doses for approximately 4 wk, and then tapering prednisone as symptoms resolve; highly effective in treatment and in prevention of blindness and other vascular complications
- consider low dose ASA

Prognosis
- increased risk of thoracic aortic aneurysm and aortic dissection
- yearly CXR ± abdominal U/S as screening

</tr>
<tr>
<td>• Family history of AS</td>
<td></td>
</tr>
<tr>
<td>• Elevated CRP</td>
<td></td>
</tr>
</tbody>
</table>

*For patients with ≥3 mc back pain and age at onset <45 yr

Etiology and Pathophysiology
- inflammation → osteopenia → erosion → ossification → osteoproliferation (syndesmophytes)

Rule of 2s
- AS occurs in 0.2% of the general population
- 2% of HLA-B27 positive individuals
- 20% of HLA-B27 positive individuals with affected family member
# Epidemiology
- M:F = 3:1; females have milder disease which may be under-recognized and more peripheral arthritis and upper spine spondylitis.
- 90-95% of patients have HLA-B27 (9% HLA-B27 positive in general population).

## Signs and Symptoms
### Axial
- Mid and lower back stiffness, prolonged morning stiffness, night pain, persistent buttock pain, painful sacroiliac joint (FABER test).
- Spinal restriction (decreased ROM): lumbar (decreased Schöber), thoracic (decreased chest wall expansion).
- Postural changes: decreased lumbar lordosis + increased thoracic kyphosis + increased cervical flexion = increased occiput to wall distance (>5 cm).

### Peripheral
- Asymmetrical large joint arthritis, most often involving lower limb.
- Enthesitis: tenderness over tibial tuberosity or Achilles tendon and plantar fascia insertions into the calcaneus.

### Extra-Articular Manifestations
- Ophthalmic: acute anterior uveitis is common (25-30% patients).
- Renal: amyloidosis (late and rare), IgA nephropathy.
- Gastrointestinal: IBD.
- Cardiac: aortitis, aortic regurgitation, pericarditis, conduction disturbances, heart failure (rare).
- Respiratory: apical fibrosis (rare).
- Neurologic: cauda equina syndrome (rare).
- Skin: psoriasis.

## Investigations
- X-ray of SI joint: "pseudowidening" of joint due to erosion and joint sclerosis → bony fusion (late), symmetric sacroiliitis.
- X-ray of spine: "squaring of edges" from erosion and sclerosis on corners of vertebral bodies (shiny corner sign) leading to ossification of outer fibres of annulus fibrosis (bridging syndesmophytes) → "bamboo spine" radiographically.
- MRI of spine: assess activity in early disease; detection of cartilage changes, bone marrow edema, bone erosions, and subchondral bone changes. Best seen on T2 STIR (short tau inversion recovery) images (suppress fat and see bone edema).

## Treatment
### Non-Pharmacological Therapy
- Prevent fusion from poor posture and disability through exercise (e.g., swimming), postural and deep breathing exercises, outpatient PT, smoking cessation.

### Pharmacological Therapy
- NSAIDs (first line of treatment).
- Glucocorticoids (topical eye drops, local injections).
- DMARDs for peripheral arthritis (sulfasalazine, MTX).
- Biologics for axial and peripheral involvement.
- Manage extra-articular manifestations.

### Surgical Therapy
- Hip replacement, vertebral osteotomy for marked deformity.

</table>
Prognosis
• spontaneous remissions and relapses are common and can occur at any age
• function may be excellent despite spinal deformity
• favourable prognosis if female and age of onset >40 yr
• early onset with hip disease may lead to severe disability; may require arthroplasty

Enteropathic Arthritis
• see Gastroenterology, Inflammatory Bowel Disease, G19
• MSK manifestations in the setting of either ulcerative colitis or Crohn’s disease include peripheral arthritis (large joint, asymmetrical), spondylitis, and hypertrophic osteoarthropathy
• non-arthritic MSK manifestations can occur 2º to steroid treatment of bowel inflammation (arthralgia, myalgia, osteoporosis, AVN)
• NSAIDs should be used cautiously as they may exacerbate bowel disease

Psoriatic Arthritis

Definition
• arthritic inflammation associated with psoriasis

Etiology and Pathophysiology
• unclear but many genetic, immunologic, and some environmental factors involved (e.g. bacterial, viral, and trauma)

Epidemiology
• psoriasis affects 1% of population
• arthropathy in 15% of patients with psoriasis
• 15-20% of patients will develop joint disease before skin lesions appear

Signs and Symptoms
• dermatologic
  • well-demarcated erythematos plaques with silvery scale
  • nail involvement: pitting, transverse or longitudinal ridging, discoloration, subungual hyperkeratosis, onycholysis, and oil drops
• musculoskeletal
  • 5 general patterns
    • asymmetric oligoarthritis (most common – 70%)
    • arthritis of DIP joints with nail changes
    • destructive (mutilans) arthritis (5%)
    • symmetric polyarthritis (similar to RA)
    • sacroiliitis and spondylitis (usually older, male patients)
  • other findings: dactylitis, enthesopathy
• ophthalmic
  • conjunctivitis, iritis (anterior uveitis)
• cardiac and respiratory (late findings)
  • aortic insufficiency
  • apical lung fibrosis
• neurologic
  • cauda equina syndrome
• radiologic
  • floating syndesmophytes
  • pencil-in-cup appearance at IP joints
  • osteolysis, periostitis

Treatment
• treat skin lesions (e.g. steroid cream, salicylic and/or retinoic acid, tar, UV light)
• NSAIDs or IA steroids
• DMARDs, biologic therapies to minimize erosive disease (use early if peripheral joint involvement)

Risks and Benefits of Tumour Necrosis Factor-alpha (TNF-α) Inhibitors in the Management of Psoriatic Arthritis (PsA): Systematic Review and Meta-analysis of Randomized Controlled Trials
J Rheumatol 2008;35:883-890
Study: Review of RCTs of adalimumab, etanercept, and infliximab used in patients with PsA.
Results: Six RCTs were included (n=1820). All 3 TNF-α inhibitors were significantly more effective than placebo on the basis of Psoriatic Arthritis Response Criteria (PsARC) and American College of Rheumatology response criteria ACR20, ACR50, and ACR70 ratings. There were no significant differences between TNF-α inhibitors and placebo in the proportions of patients who withdrew for any reason (RR 0.48, 95% CI 0.20-1.18), or withdrawal due to adverse events (RR 2.14, 95% CI 0.73-6.27), serious adverse events (RR 0.98, 95% CI 0.56-1.77), or upper respiratory tract infections (RR 0.91, 95% CI 0.55-1.52). Pooled rates for injection site reactions were significantly higher for adalimumab and etanercept than for placebo (RR 2.48, 95% CI 1.16-5.29), but there was no significant difference in the proportion of patients experiencing infusion reactions with infliximab (RR 1.03, 95% CI 0.48-2.20) compared to placebo. Indirect analysis did not demonstrate any significant differences between the TNF-α inhibitors.

Conclusions: TNF-α inhibitors are effective treatments for PsA with no important added risks associated with their short-term use. There is still a need for long-term risk-benefit assessment of use of these drugs for the management of PsA.
Table 29. CASPAR Criteria for PsA*

<table>
<thead>
<tr>

<td>Juxta articular bone formation on hand or foot x-rays</td>
</tr>
</tbody>
</table>

* To meet the CASPAR (ClASsification criteria for Psoriatic ARthritis) criteria, a patient must have inflammatory articular disease (joint, spine, or enthesitis) with ≥2 points from the above 5 categories.

Reactive Arthritis

Definition

- two meanings
  1. reactive arthritis: a sterile arthritis following an infection (e.g. rheumatic fever, post-viral arthritis, etc.), not used frequently by rheumatologists
  2. reactive arthritis (ReA): one of the seronegative spondyloarthropathies in which patients have a peripheral arthritis (≥1 mo duration) accompanied by one or more extra-articular manifestations that appears shortly after certain infections of the GI or GU tracts

Etiology

- onset following an infectious episode either involving the GI or GU tract
  - GI: Shigella, Salmonella, Campylobacter, Yersinia species
  - GU: Chlamydia (isolated in 16-44% of ReA cases), Mycoplasma species
- acute clinical course
  - 1-4 wk post-infection
  - lasts weeks to years
  - often recurring
  - spinal involvement persists

Epidemiology

- in HLA-B27 patients, axial > peripheral involvement
- M>F

Signs and Symptoms

- musculoskeletal
  - peripheral arthritis, asymmetric pattern, spondylitis, Achilles tendinitis, plantar fasciitis, dactyitis
- ophthalmic
  - iritis (anterior uveitis), conjunctivitis
- dermatologic
  - keratoderma blennorrhagium (hyperkeratotic skin lesions on palms and soles) and balanitis cinerinata (small, shallow, painless ulcers of glans penis and urethral meatus) are diagnostic
- gastrointestinal
  - oral ulcers, diarrhea
- urethritis and cervicitis
  - sterile pyuria; presence not related to site of initiating infection

Investigations

- diagnosis is clinical plus laboratory
- blood work: normocytic, normochromic anemia, and leukocytosis
- sterile cultures
- serology: HLA-B27 positive

Treatment

- antibiotics for non-articular infections
- NSAIDs, physical therapy, exercise
- local therapy
  - joint protection
  - IA steroid injection
  - topical steroid for ocular involvement
- systemic therapy
  - corticosteroids, sulfasalazine, MTX (for peripheral joint involvement only)
  - TNF-α inhibitors for spinal inflammation

Prognosis

- self-limited, typically 3-5 mo, varies based on pathogen and patient’s genetic background
- chronic in 15-20% of cases
Crystal-Induced Arthropathies

#### Gout

**Definition**
- derangement in purine metabolism resulting in hyperuricemia; monosodium urate crystal deposits in tissues (tophi) and synovium (microtophi)

**Etiology and Pathogenesis**
- sources of uric acid: diet and endogenous synthesis
  - hypoxanthine $\rightarrow$ xanthine $\rightarrow$ uric acid
  - both steps catalyzed by xanthine oxidase

**Hyperuricemia**
- primary or genetic
  - mostly due to idiopathic renal underexcretion (90%)
  - also idiopathic overproduction or abnormal enzyme production/function
- secondary
  - dietary excess (particularly high consumption of beer, seafood, and meat)
  - underexcretion (<90%): renal failure, drugs, systemic conditions
  - overproduction (<10%): increased nucleic acid turnover states (e.g. malignancy, post-chemotherapy)

- sudden changes (increasing or decreasing) in uric acid concentration are more important than absolute values
  - acute gout can occur with normal serum uric acid
  - changes in pH, temperature, or initiation of antihyperuricemics may precipitate an acute gouty attack
- common precipitants: alcohol, dietary excess, dehydration, drugs (e.g. thiazide and loop diuretics), trauma, illness, surgery, starting xanthine oxidase inhibitor therapy
- other associated conditions: HTN, obesity, DM, starvation

**Epidemiology**
- most common in males >45 yr
- extremely rare in premenopausal females

**Signs and Symptoms**
- single episode progressing to recurrent episodes of acute inflammatory arthritis
- acute gouty arthritis
  - severe pain, redness, joint swelling, usually involving lower extremities
  - joint mobility may be limited
  - attack will subside spontaneously within several days to weeks; may recur
- tophi
  - urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
  - common sites: first MTP, ear helix, olecranon bursae, tendon insertions (common in Achilles tendon)
- kidney
  - gouty nephropathy
  - uric acid calculi

**Investigations**
- joint aspirate: >90% of joint aspirates show crystals of monosodium urate (negatively birefringent, needle-shaped)
- x-rays may show tophi as soft tissue swelling, punched-out lesions, erosion with “over-hanging”
- X-rays may show tophi as soft tissue swelling, punched-out lesions, erosion with “over-hanging”
- urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
- common sites: first MTP, ear helix, olecranon bursae, tendon insertions (common in Achilles tendon)
- kidney
- gouty nephropathy
- uric acid calculi

- Normal or low uric acid levels do not rule out gout

- The majority of people with hyperuricemia do not have gout
- An acute gout attack may mimic cellulitis; however, joint mobility is preserved in cellulitis
- Gout often affects more than one joint (i.e. ankle, midfoot, and MTPs)

- Allopurinol can be used in patients with mild/moderate disease
- NSAIDs, corticosteroids, colchicine
- X-rays may show tophi as soft tissue swelling, punched-out lesions, erosion with “over-hanging”
**Treatment**

- **acute gout**
  - NSAIDs: high dose, then taper as symptoms improve
  - corticosteroids: IA, oral, or intra-muscular (if renal, cardiovascular, or GI disease and/or if NSAIDs contraindicated or failed)
  - colchicine within first 12 h but effectiveness limited by narrow therapeutic range
  - allopurinol can worsen an acute attack (do not start during acute flare)

- **chronic gout**
  - conservative
    - avoid foods with high purine content (e.g. visceral meats, sardines, shellfish, beans, peas)
    - avoid drugs with hyperuricemic effects (e.g. pyrazinamide, ethambutol, thiazide, alcohol)
  - medical
    - antihyperuricemic drugs (allopurinol and febuxostat): decrease uric acid production by inhibiting xanthine oxidase
    - uricosuric drugs (probenecid, sulfinpyrazone): use if failure on or intolerant to allopurinol; do not use in renal failure
    - prophylaxis prior to starting antihyperuricemic drugs (colchicine/low-dose NSAID)
    - in renal disease secondary to hyperuricemia, use low-dose allopurinol and monitor Cr

- indications for treatment with antihyperuricemic medications include
  - recurrent attacks, tophi, bone erosions, urate kidney stones
  - perhaps in renal dysfunction with very high urate load (controversial)

---

**Pseudogout (Calcium Pyrophosphate Dihydrate Disease)**

**Definition**
- joint inflammation caused by calcium pyrophosphate crystals

**Etiology and Pathophysiology**
- acute inflammatory arthritis due to phagocytosis of IgG-coated CPPD crystals by neutrophils and subsequent release of inflammatory mediators within joint space
- more frequently polyarticular
- slower in onset in comparison to gout, lasts up to 3 wk but is self-limited

**Risk Factors**
- old age, advanced OA, neuropathic joints
- other associated conditions: hyperparathyroidism, hypothyroidism, hypomagnesemia, hypophosphatasia (low ALP), DM, hemochromatosis

**Signs and Symptoms**
- affects knees, wrists, MCPs, hips, shoulders, elbows, ankles, big toe
- multiple manifestations
  - asymptomatic crystal deposition (seen on radiograph only)
  - acute crystal arthritis (self-limited flares of acute inflammatory arthritis resembling gout)
  - pseudo-OA (progressive joint degeneration, sometimes with episodes of acute inflammatory arthritis)
  - pseudo-RA (symmetrical polyarticular pattern with morning stiffness and constitutional symptoms)
- acute may be triggered by dehydration, acute illness, surgery, trauma

**Investigations**
- must aspirate joint to rule out septic arthritis, gout
- CPPD crystals: present in 60% of patients, often only a few crystals, positive birefringence (blue) and rhomboid shaped
- x-rays show chondrocalcinosis in 75%: radiodensities in fibrocartilaginous structures (e.g. knee menisci) or linear radiodensities in hyaline articular cartilage

**Treatment**
- joint aspiration, rest, and protection
- NSAIDs: also used for maintenance therapy
- prophylactic colchicine PO (controversial)
- IA or oral steroids to relieve inflammation
Non-Articular Rheumatism

Definition
• disorders that primarily affect soft tissues or periarticular structures
  • includes bursitis, tendinitis, tenosynovitis, fibromyalgia, and PMR

Polymyalgia Rheumatica

Definition
• characterized by pain and stiffness of the proximal extremities (girdle area)
• closely related to GCA (15% of patients with PMR develop GCA)
• no muscle weakness

Table 31. PMR Classification Criteria Scoring Algorithm*

<table>

*Required criteria: age >50 yr, bilateral shoulder aching, and abnormal ESR/CRP
* A score of 4 or more is categorized as PMR in the algorithm without U/S and a score of 5 or more is categorized as PMR in the algorithm with U/S
**Optional U/S criteria
Ann Rheum Dis 2012;71:484-492

Epidemiology
• incidence 50 per 100,000 per year in those >50 yr
• age of onset typically >50 yr, F:M = 2:1

Signs and Symptoms
• constitutional symptoms prominent (fever, weight loss, malaise)
• pain and stiffness of symmetrical proximal muscles (neck, shoulder and hip girdles, thighs)
• gel phenomenon (stiffness after prolonged inactivity)
• physical exam reveals tender muscles, but no weakness or atrophy

Investigations
• blood work: often shows anemia, elevated platelets, elevated ESR and CRP, and normal CK; up to 5% of PMR reported with normal inflammatory markers

Treatment
• goal of therapy: symptom relief
• start with prednisone dose of 15-20 mg PO OD, reconsider diagnosis if no response within several days
• taper slowly over 2 yr period monitoring ESR and symptoms closely
• relapses should be diagnosed and treated on clinical basis; do not treat a rise in ESR as a relapse
• treat relapses aggressively (50% relapse rate)
• monitor for steroid side effects, glucocorticoid-induced osteoporosis prevention, and follow for symptoms of GCA

Most patients are treated for up to 2 yr
**Fibromyalgia**

**Definition**
- chronic (>3 mo), widespread (axial, left- and right-sided, upper and lower segment), non-articular pain with characteristic tender points

**Diagnosis**

**Table 32. 2010 ACR Preliminary Diagnostic Criteria for Fibromyalgia**

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Widespread Pain Index = number of areas in which the patient had pain over the last week (max score = 19):</td>
<td>A patient satisfies diagnostic criteria for fibromyalgia if the following 3 conditions are met:</td>
</tr>
<tr>
<td>L and R: shoulder girdle, upper arm, lower arm, hip, upper leg, lower leg, jaw</td>
<td>1. Widespread Pain Index (WPI) ≥7 and Symptom Severity (SS) scale score ≥5 or WPI 3–6 and SS scale score ≥9</td>
</tr>
<tr>
<td>One Area: chest, abdomen, upper back, lower back, neck</td>
<td>2. Symptoms have been present at a similar level for at least 3 mo</td>
</tr>
<tr>
<td>Symptom Severity Score = sum of:</td>
<td>3. The patient does not have a disorder that would otherwise explain the pain</td>
</tr>
<tr>
<td>a) severity of fatigue</td>

<td></td>
</tr>
</tbody>
</table>

*Arthritis Care and Research 2010;62(s5):S60-S610*

**Epidemiology**
- F:M = 3:1
- primarily ages 25-45 yr, some adolescents
- prevalence of 2-5% in general population
- overlaps with chronic fatigue syndrome and myofascial pain syndrome
- strong association with psychiatric illness

**Signs and Symptoms**
- widespread aching, stiffness
- easy fatigability
- sleep disturbance: non-restorative sleep, difficulty falling asleep, and frequent waking
- symptoms aggravated by physical activity, poor sleep, emotional stress
- patient feels that joints are diffusely swollen although joint examination is normal
- neurologic symptoms of hyperalgesia, paresthesias
- associated with irritable bowel or bladder syndrome, migraines, tension H/A, restless leg syndrome, obesity, depression, and anxiety
- physical exam should reveal only tenderness with palpation of soft tissues, with no specificity for trigger/tender points

**Investigations**
- blood work: includes TSH and ESR; all typically normal unless unrelated, underlying illness present
- serology: do not order ANA or RF unless there is clinical suspicion for a connective tissue disease
- laboratory sleep assessment

**Differential Diagnosis**
- diagnosis of exclusion
- rule out other disorders by history and physical exam (RA, SLE, PMR, myositis, hypothyroidism, hyperparathyroidism, neuropathies)

**Treatment**
- non-pharmacological therapy
  - education
  - exercise program (walking, aquatic exercises), physical therapy (good posture, stretching, muscle strengthening, massage)
  - stress reduction, CBT
  - no evidence for alternative medicine such as biofeedback, meditation, acupuncture

**A 14 Week, RCT of Pregabalin in Patients with Fibromyalgia**

**Study:** Multicentre RCT. 750 patients with fibromyalgia with pain score of <40 mm on the visual analog scale (VAS) were assigned to placebo or pregabalin (300 mg, 450 mg, or 600 mg) daily for 12 wk.

**Primary Outcome:** Change in the mean pain score derived from the subject’s daily pain diary as measured at the patient’s baseline to the end point of the study.

**Results:** Patients treated with 300, 450 and 600 mg/d pregabalin showed a statistically significant improvement in the end point mean pain score compared with placebo-treated subjects. Discontinuations due to adverse events were 12%, 16%, 22%, and 26% in placebo, 300 mg/d, 450 mg/d, and 600 mg/d respectively. The 450 and 600 mg/d groups were significantly different from placebo (p=0.0001).

**Conclusions:** Pregabalin at 300 mg/d, 450 mg/d, and 600 mg/d showed statistically significant response rates as compared to placebo although discontinuation rates for the 450 mg/d and 600 mg/d regimens were significantly higher as compared to placebo.

**Exercise for Treating Fibromyalgia Syndrome**

**Study:** Systematic review of exercise training including cardiorespiratory endurance, muscle strengthening, and flexibility for global well-being and physical function in patients with fibromyalgia.

**Result:** 34 studies were included (n=2,276).

**Conclusion:** Moderate aerobic cardiorespiratory exercise improves function and well-being in patients with fibromyalgia. Benefits from muscle strengthening and flexibility require additional research to delineate benefits.
• pharmacological therapy
  • low dose tricyclic antidepressant (e.g. amitriptyline)
  • for sleep restoration
  • select those with lower anticholinergic side effects
  • SNRI: duloxetine, milnacipran
  • anticonvulsant: pregabalin, gabapentin
  • analgesics may be beneficial for pain that interferes with sleep (NSAIDs, not narcotics)

Prognosis
• variable; usually chronic, unless diagnosed and treated early

### Adult Onset Still’s Disease

#### Definition
• systemic inflammatory condition (ANA and RF negative) with fevers and characteristic rash, numerous systemic symptoms, and may have severe arthritis

#### Etiology and Pathophysiology
• idiopathic; infectious triggers likely – various viruses and bacteria have been implicated
• stress increases risk

#### Epidemiology
• F>M; age of onset typically 16-40, approximately 1 per 100,000

#### Signs and Symptoms
• classic triad of symptoms
  • high-spiking fevers (95.7% of patients, typically T = 39°C, <4 h duration, quotidian pattern)
  • characteristic “salmon rash” (~72% of patients, on proximal limbs + trunk)
  • arthralgia/arthritis (64-100%)
    • arthritis is symmetric, typically affects large joints, i.e. wrists, knees and ankles, may involve PIP and DIPs, elbow, MTPs
  • sore throat, myalgias and serositis may also occur
  • liver abnormalities ± hepatomegaly (50-75% patients)
  • splenomegaly (44%)

#### Classification
• numerous classification systems proposed

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Need 5 criteria for diagnosis, at least 2 major. Exclusion criteria: infection, malignancy, rheumatic disease

#### Investigations
• ANA and RF negative
• markedly elevated ESR, CRP, ferritin (typically >1000 ng/mL)
  • total ferritin >5x ULN = 80% sensitive, 41% specific
  • anemia, thrombocytosis, leukocytosis may occur
  • transaminases, LDH may be elevated

#### Treatment
• biologics (anti-IL-1 and anti-IL-6 agents)
• begin management with low-dose glucocorticoids ± MTX

</tbody>
</table>

### Other Treatments

- Combination analgesics (acetaminophen + codeine, acetaminophen + NSAIDs)
  - Enhanced short-term effect compared to acetaminophen alone
  - More adverse effects: sedation, constipation, nausea, GI upset
- IA corticosteroid injection
  - Short-term (weeks-months) decrease in pain and improvement in function
  - Used for management of an IA inflammatory process when infection has been ruled out
- IA hyaluronic acid q6mo
  - For mild-moderate OA of the knees, however, little supporting evidence, and not considered to be effective
  - Precaution with chicken/egg allergy
- Topical NSAIDs
  - 25% wt/wt topical diclofenac (Pennsaid®)
    - May use for patients who fail acetaminophen treatment and who wish to avoid systemic therapy
- Capsaicin cream
  - Limited clinical studies
  - No regulation by Health Canada
- Glucosamine sulfate ± chondroitin
  - Limited clinical studies
  - No regulation by Health Canada

**GOUT**

| Febuxostat vs. allopurinol | NEJM 2005; 353:2450-61 | Febuxostat is more effective than allopurinol at lowering serum urate, and has similar effectiveness on flare reduction |

**ANKYLOSING SPONDYLITIS**

| Adalimumab | Arthritis Rheum 2006; 54:2136-46 | Adalimumab induced partial remission in 22% of AS patients |
| ASSET (rituximab) | Arthritis Rheum 2005; 52:582-91 | Sixty percent of patients treated with rituximab had a clinical response to the medication |
| ATLAS (adalimumab) | J Rheumatol 2008; 35:1346-53 | Compared to placebo, adalimumab significantly reduces pain and fatigue in AS patients |
| Infliximab in AS | Lancet 2005; 36:1187-93 | Infliximab induces regression of symptoms in 50% of patients and is superior to placebo |
| SPINE (etanercept) | Ann Rheum Dis 2011; 70:799-804 | Etanercept has short-term efficacy for patients with advanced AS and reduces disease severity |
| Salsalazine | Arthritis Rheum 1995; 38:618-27 | Salsalazine is superior to placebo in treatment of patients with seronegative spondyloarthropathy |

• recall that the anatomical position of the penis is erect; therefore, the anatomical ventral side of the penis appears to be the dorsal side of the flaccid penis.
Urologic History

- follow the OPQRSTUW approach
  - note that pain may not be limited to the genital region (e.g. lower abdomen, CVA)
- inquire about risk factors: past urologic disease (e.g. UTI, stones, STI, cancers, anatomic abnormalities, family Hx, medications, lifestyle factors, trauma, previous surgical procedures)
- urinary habits
  - frequency of voiding, quality of urine, volume of voids, incontinence, nocturia
  - specific urinary symptoms include
    - storage symptoms: frequency, nocturia, urgency
    - voiding symptoms: straining, hesitancy, dysuria, intermittency, post-void dribbling, reduced stream, feeling of incomplete voiding
    - hematuria: part of stream during which bleeding occurs, blood clots
    - incontinence: rushing to washroom (urge); leakage with coughing, sneezing, laughing (stress); constant dribbling (overflow)
- sexual function
  - scrotal mass: see Scrotal Mass, U29
  - ED: see Erectile Dysfunction, U30
  - infertility: see Infertility, U34
- risk factors
  - past urologic disease (e.g. UTI, stones, cancers, STI), anatomic abnormalities, trauma, previous surgical procedures, medications, family Hx, lifestyle factors
- associated symptoms
  - N/V
  - bowel dysfunction
- constitutional symptoms
  - fever, chills, unintentional weight loss, night sweats, fatigue, malaise

Always ask about sexual function on history. Change in erectile function can be one of the first symptoms that there is concomitant vascular disease. If there is new onset ED, consider screening for DM and CAD risk factors.
Hematuria (Blood in the Urine)

Macroscopic (Gross) Hematuria

Definition
• blood in the urine that can be seen with the naked eye

Classification
• see Nephrology, NP20

History
• inquire about timing of hematuria in urinary stream
  • initial: anterior urethra
  • terminal: bladder neck and prostatic urethra
  • total: bladder and/or above

Investigations
• CBC (rule out anemia, leukocytosis), electrolytes, Cr, BUN, INR, PTT
• urine studies
  • U/A, C&S, cytology
• imaging
  • CT (with contrast) has largely replaced IVP to investigate upper tracts
    • consider contraindications to contrast: allergy, renal insufficiency
    • U/S alone is not sufficient
  • cystoscopy to investigate lower tract (possible retrograde pyelogram)

Acute Management of Severe Bladder Hemorrhage
• manual irrigation via catheter with normal saline to remove clots
• CBI using large (22-26 Fr) 3-way Foley to help prevent clot formation
• cystoscopy if active bleeding
  • identify resectable tumours
  • coagulate obvious sites of bleeding
• refractory bleeding
  • intravesical agents
    • continuous intravesical irrigation with 1% aluminum potassium sulfate solution as needed
    • intravesical instillation of 1% silver nitrate solution
    • intravesical instillation of 1-4% formalin (requires GA and pre-procedure cystogram to rule out reflux)
• embolization or ligation of iliac arteries
• cystectomy and diversion (rarely performed)

Common Urologic Causes of Hematuria can be Classified as:
TICS
• Trauma/Tumour/Toxins
• Infection/Inflammatory
• Calculi/Cysts
• Surgery/Sickle cell and other hematological causes

Upper Tract Imaging Options
CT Urography (CTU): Optimal test for renal parenchyma, calculi, and infections. Involves exposure to radiation and IV contrast. Assess kidney function, allergies prior to use of contrast
U/S: Superior to IVP for evaluation of renal parenchyma and renal cysts. Limited sensitivity for UCC and small renal masses. U/S alone is not sufficient for upper tract imaging
Intravenous Pyelogram (IVP): Traditional option but rarely used (replaced by CTU). Reasonable sensitivity for UCC, but poor sensitivity for RCC
Microscopic Hematuria

Definition
- blood in the urine that is not visible to the naked eye
- >3 RBCs/HPF on urinalysis of at least two separate samples

Figure 6. Workup of asymptomatic microscopic hematuria
Based on CUA Guidelines. Alternatively, the AUA recommends cystoscopy and CT urogram for all patients with confirmed microscopic hematuria; follow-up for negative workup is urinalysis yearly for two years, with repeat anatomic evaluation if microscopic hematuria persists

Lower Urinary Tract Dysfunction

- see Gynecology, GY37 for relevant female topics

Voiding

- two phases of lower urinary tract function
  1. storage phase (bladder filling and urine storage)
     • accommodation and compliance
     • no involuntary contraction
  2. voiding phase (bladder emptying)
     • coordinated detrusor contraction
     • synchronous relaxation of outlet sphincters
     • no anatomic obstruction
- voiding dysfunction can therefore be classified as
  • failure to store: due to bladder or outlet
  • failure to void: due to bladder or outlet
- three types of symptoms
  • storage (formerly known as irritative)
  • voiding (formerly known as obstructive)
  • post-voiding

Urinary Incontinence

Definition
- involuntary leakage of urine

Etiology
- urgency incontinence
  • detrusor overactivity
    • CNS lesion, inflammation/infection (cystitis, stone, tumour), bladder neck obstruction (tumour, stone), BPH, idiopathic

Lower Urinary Tract Symptoms (LUTS)
- Storage (FUND)
  - Frequency
  - Urgency
  - Nocturia
- Dysuria
- Voiding (SHED)
  - Stream changes
  - Hesitancy
  - Incomplete Emptying
  - Dribbling
decreased compliance of bladder wall (inability to store urine)
- CNS lesion, fibrosis
- sphincter/urethral problem
- stress urinary incontinence (SUI)
- common in women; seen in men after prostate cancer treatment or pelvic operations
- urethral hypermobility
- weakened pelvic floor and musculofascial urethral and vaginal supporting mechanisms allows bladder neck and urethra to descend with increased intra-abdominal pressure
- urethra is pulled open by greater motion of posterior wall of outlet relative to anterior wall
- associated with childbirth, pelvic surgery, aging, levator muscle weakness, obesity
- intrinsic sphincter deficiency (ISD): weakness of the urethra and associated smooth and striated muscle elements
- pelvic surgery, neurologic problem, aging and hypoestrogen state
- ISD and urethral hypermobility can co-exist
- mixed incontinence
- combination of stress and urgency incontinence
- overflow incontinence
- is a term sometimes used to describe urinary incontinence as a complication of urinary retention; for causes of urinary retention see Table 4
- use of the term should be accompanied by the associated pathophysiology (e.g. BPH with overflow incontinence)

Epidemiology
- variable prevalence in women: 25-45%
- F:M = 2:1
- more frequent in the elderly, affecting 5-15% of those living in the community and 50% of nursing home residents

Table 3. Urinary Incontinence: Types and Treatments

</tbody>
</table>

Clinical Features
- suprapubic pain
- palpable and/or percussible bladder (suprapubic)
- possible purulent/bloody meatal discharge
- increased size of prostate or reduced anal sphincter tone on DRE
- neurological: presence of abnormal or absent deep tendon reflexes, reduced "anal wink", saddle anesthesia
**Investigations**
- CBC, electrolytes, Cr, BUN, U/A and urine C&S, U/S, cystoscopy, urodynamic studies, PVR

**Treatment**
- treat underlying cause
- catheterization
  - acute retention
    - immediate catheterization to relieve retention; leave Foley in to drain bladder; follow-up to determine cause; closely monitor fluid status and electrolytes (risk of POD)
  - chronic retention
    - intermittent catheterization by patient may be used; definitive treatment depends on etiology
- suprapubic tube placement
- for post-operative patients with retention:
  - encourage ambulation
  - α-blockers to relax bladder neck outlet
  - may need catheterization
  - definitive treatment will depend on etiology

---

**Benign Prostatic Hyperplasia**

**Definition**
- periurethral hyperplasia of stroma and epithelium in prostatic transition zone
- prostatic smooth muscle cells play a role in addition to hyperplasia

**Etiology**
- etiology unknown
  - DHT required (converted from testosterone by 5-α reductase)
  - possible role of impaired apoptosis, estrogens, other growth factors
  - genetic: increased risk in 1st degree relatives and twin studies

**Epidemiology**
- age-related, extremely common (50% of 50 yr olds, 80% of 80 yr olds)
- 25% of men will require treatment

**Clinical Features**
- result from outlet obstruction and compensatory changes in detrusor function
- voiding and storage symptoms
- DRE
  - prostate is smooth, rubbery, and symmetrically enlarged
- complications
  - retention
  - overflow incontinence
  - hydronephrosis
  - renal insufficiency
  - infection
  - gross hematuria
  - bladder stones

**Investigations**
- Hx, assessing LUTS and impact on QOL
  - may include self-administered questionnaires (IPSS or AUA symptom index for severity, progression, and treatment response)
- P/E, including DRE
- U/A to exclude UTI
- Cr to assess renal function
- renal U/S to assess for hydronephrosis
- PSA to rule out malignancy (see *Prostate Cancer Screening*, U25)
- uroflowmetry to measure flow rate (optional)
- PVR (optional)
- consider cystoscopy or transrectal ultrasound prior to potential surgical management to evaluate outlet and prostate volume
- biopsy if suspicious for malignancy, i.e. elevated PSA or abnormal DRE

<td></td>
</tr>
</tbody>
</table>

Urethral Stricture

Definition
- Decrease in urethral calibre due to scar formation in urethra (may also involve corpus spongiosum)
- M>F

Etiology
- Congenital
  - Failure of normal canalization (i.e. posterior urethral valves)
- Trauma
  - Instrumentation/catheterization (most common)
  - External trauma (e.g. burns, straddle injury)
  - Foreign body
- Infection
  - Long-term indwelling catheter
  - STI (gonococcal or chlamydial disease)
- Inflammation
  - Balanitis xerotica obliterans (BXO; lichen sclerosis or chronic progressive sclerosing dermatosis of the male genitalia) causing meatal and urethral stenosis

Clinical Features
- Voiding symptoms
- Urinary retention
- Hydrenephrosis
- Related infections: recurrent UTI, secondary prostatitis/epididymitis

Investigations
- Laboratory findings
  - Flow rates <10 mL/s (normal ~20 mL/s) on uroflowmetry
  - Urine culture usually negative, but U/A may show pyuria
- Radiologic findings
  - RUG and VCUG will demonstrate location
- Cystoscopy

Treatment
- Urethral dilatation
  - Temporarily increases lumen size by breaking up scar tissue
  - Healing will often reform scar tissue, recurrence of stricture
- Visual internal urethrotomy (VIU)
- Endoscopically incise stricture
- Equal success rates to dilation with midbulbar strictures <2 cm
- High rate of recurrence (30-80%), avoid in younger patients
- Open surgical reconstruction
  - Complete stricture excision with anastomosis, ± urethroplasty depending on location and size of stricture

BPH Surgery

Absolute Indication
- Renal failure with obstructive uropathy
- Refractory urinary retention

Relative Indications
- Recurrent UTIs
- Recurrent hematuria refractory to medical treatment
- Renal insufficiency (rule out other causes)
- Bladder stones

BPH Surgery: Absolute Indication

- Men with planned cataract surgery should avoid starting α-adrenergic antagonists until after their surgery due to the risk of intraoperative floppy iris syndrome

Finasteride for Benign Prostatic Hyperplasia

Purpose: To examine the effectiveness and safety of finasteride versus placebo or other active controls for the treatment of urinary tract symptoms.

Summary of Findings:
1. Finasteride improved urinary symptoms more than placebo in trials >1 yr duration and significantly lowered the risk of BPH progression.
2. Compared with α-blockers, finasteride was less effective than either doxazosin or terazosin, but equally as effective as tamulosin.
3. Symptom improvement with finasteride + doxazosin is equal to doxazosin alone.
4. Finasteride treatment resulted in an increased risk of ejaculatory disorder, impotence and lowered libido compared with placebo.
5. Compared with doxazosin and tamulosin, finasteride had a lower risk of asthma, dizziness, and postural hypotension.

Microwave Thermotherapy for Benign Prostatic Hyperplasia

Purpose: To evaluate the efficacy and safety of microwave thermotherapy for the treatment of benign prostatic obstruction.

Selection Criteria: RCTs evaluating transurethral microwave therapy (TUMT) for men with symptomatic BPH with multiple comparison groups.

Results: 15 studies, 1,585 patients, mean age 66.8 yr, 3-60 mo duration. Mean urinary symptom scores decreased by 95% with TUMT and 77% with TURP.

The pooled mean peak urinary flow increased by 70% with TUMT and 119% with TURP. Compared with TURP, TUMT was associated with decreased risks for reoperation/splenorrhaphy, treatment for strictures, hematuria, blood transfusions and transurethral resection syndrome, but increased risk for dysuria, urinary retention and retreatment for BPH symptoms.

Conclusions: Overall, microwave thermotherapy techniques are effective alternatives to TURP and α-blockers for treating symptomatic BPH, although less effective than TURP in improving symptom score and urinary flow.
Neurogenic Bladder

Definition
• malfunctioning urinary bladder due to deficiency in some aspect of its innervation

Neurophysiology

Table 6. Efferent Sympathetic, Parasympathetic, and Somatic Nerve Supply

<table>
<thead>
<tr>
<th>Nerve Fibres</th>
<th>Nerve Roots</th>
<th>Neurotransmitter/Receptor</th>
<th>Target</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Parasympathetic</td>
<td>S2-4</td>
<td>ACh/Muscarinic (M2, M3)</td>
<td>Detrusor</td>
</tr>
</tbody>
</table>

• stretch receptors in the bladder wall relay information to PMC and activate micturition reflex (normally inhibited by cortical input)
  • micturition
    • stimulation of parasympathetic neurons (bladder contraction)
    • inhibition of sympathetic and somatic neurons (internal and external sphincter relaxation, respectively)
  • urine storage
    • opposite of micturition
• voluntary action of external sphincter (pudendal nerve roots S2-S4) can inhibit urge to urinate
• cerebellum, basal ganglia, thalamus, and hypothalamus all have input at PMC in the brainstem

Classification of Neurologic Voiding Dysfunction
• neuropathic detrusor overactivity (formerly termed detrusor hyperreflexia)
  • lesion above PMC (e.g. stroke, tumour, MS, Parkinson’s disease)
  • loss of voluntary inhibition of voiding
  • intact pathway inferior to PMC maintains coordination of bladder and sphincter
• detrusor sphincter dyssynergia (DSD)
  • suprasacral lesion of spinal cord (e.g. trauma, MS, arteriovenous malformation, transverse myelitis)
  • loss of coordination between detrusor and sphincter (detrusor contracts on closed sphincter and vice versa)
• component of detrusor overactivity as well
• detrusor atony/areflexia
  • lesion of sacral cord or peripheral efferents (e.g. trauma, DM, disc herniation, MS, congenital spinal cord abnormality, post abdominoperineal resection)
  • flaccid bladder which fails to contract
  • may progress to poorly compliant bladder with high pressures
• peripheral autonomic neuropathy
  • deficient bladder sensation → increasing residual urine → decompensation (e.g. DM, neurosyphilis, herpes zoster)
• muscular lesion
  • can involve detrusor, smooth/striated sphincter

Neuro-Urologic Evaluation
• Hx and P/E (urologic and general neurologic)
• U/A, renal profile
• imaging
  • IVP (less used), U/S to rule out hydronephrosis and stones
• cystoscopy
• urodynamic studies
  • uroflowmetry to assess flow rate, pattern
  • filling CMG to assess capacity, compliance, detrusor overactivity
  • voiding CMG (pressure-flow study) to assess bladder contractility and extent of bladder outlet obstruction
  • video study to visualize bladder/bladder neck/urethra during CMG using x-ray contrast
• EMG ascertains presence of coordinated or uncoordinated voiding, allows accurate diagnosis of DSD

Treatment
• goals of treatment
  • prevent renal failure
  • prevent infections
  • achieve social continence
• clean intermittent catheterization (CIC)
• treatment options depend on status of bladder and urethra
  • bladder hyperactivity → anticholinergic medications to relax bladder (see Urinary Incontinence, U5)
    • if refractory
      – botulinum toxin injections into bladder wall
      – occasionally augmentation cystoplasty (enlarging bladder volume and improving compliance by grafting section of detubularized bowel onto the bladder)
      – occasionally urinary diversion (ileal conduit or continent diversion) in severe cases if bladder management unsuccessful
  • flaccid bladder → CIC

### Dysuria

**Definition**
- painful urination

**Etiology**

<table>
<thead>
<tr>
<th>Table 7. Differential Diagnosis of Dysuria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infectious</td>
</tr>
<tr>
<td>Neoplasm</td>
</tr>
<tr>
<td>Calculi</td>

<tr>
<td>Inflammatory</td>
</tr>
<tr>
<td>Hormonal</td>
</tr>
<tr>
<td>Trauma</td>
</tr>
<tr>
<td>Psychogenic</td>
</tr>
<tr>
<td>Other</td>
</tr>
</tbody>
</table>

**Investigations**
- focused Hx and P/E to determine cause (fever, d/c, conjunctivitis, CVA tenderness, back/joint pain)
  - any d/c (urethral, vaginal, cervical) should be sent for gonococcus/chlamydia testing; wet mount if vaginal d/c
  - U/A and urine C&S
  - if suspect infection, may start empiric ABx treatment (see Table 8, U11)
  - ± imaging of urinary tract (tumour, stones)

### Hydronephrosis

**Definition**
- dilation of the renal pelvis and calyces caused by the impairment in antegrade urine flow

**Etiology**
- mechanical
  - congenital: see Congenital Abnormalities, U35
  - acquired
    - intrinsic: trauma, inflammation and bleeding, calculi, urologic neoplasms, BPH, urethral stricture, phimosis, previous urological surgery
    - extrinsic: trauma, neoplasms (uterine fibroid, colorectal, uterine, and cervical malignancies; lymphoma), aortic aneurysm, pregnancy (gravid uterus)
  - functional
    - neuropathic: neurogenic bladder, diabetic neuropathy, spinal cord disease
    - pharmacologic: anticholinergics, α-adrenergic agonists
    - hormonal: pregnancy (progesterone decreases ureteral tone)

**Investigations**
- focused Hx, inquiring about pain (flank, lower abdomen, testes, labia), U/O, medication use, pregnancy, trauma, fever, Hx of UTIs, calculi, and PID and urological surgery
• CBC, electrolytes, Cr, BUN, U/A, C&S
• imaging studies (U/S is >90% sensitive and specific)
  ▪ MAG3 diuretic renogram: evaluates differential renal function and demonstrates if functional obstruction exists

**Treatment**
• hydrenephrosis can be physiologic
• treatment should be guided at improving symptoms, treating infections, or improving renal function
• urgent treatment may require percutaneous nephrostomy tube or ureteral stenting to relieve pressure

---

**Post-Obstructive Diuresis**

**Definition**
• polyuria resulting from relief of severe chronic obstruction
• >3 L/24 h or >200 cc/h over each of two consecutive hours

**Pathophysiology**
• **physiologic POD** secondary to excretion of retained urea, Na⁺, and H₂O (high osmotic load) after relief of obstruction
  ▪ self-limiting; usually resolves in 48 h with PO fluids but may persist to pathologic POD
• **pathologic POD** is a Na⁺-wasting nephropathy secondary to impaired concentrating ability of the renal tubules due to
  ▪ decreased reabsorption of NaCl in the thick ascending limb and urea in the collecting tubule
  ▪ increased medullary blood flow (solute washout)
  ▪ increased flow and solute concentration in the distal nephrons

**Management**
• admit patient and closely monitor hemodynamic status and electrolytes (Na⁺ and K⁺ q6-12h and replace prn; follow Cr and BUN to baseline)
• monitor U/O q2h and ensure total fluid intake <U/O by replacing every 1 mL U/O with 0.5 mL 1/2 NS IV (PO fluids if physiologic POD)
• avoid glucose-containing fluid replacement (iatrogenic diuresis)

---

**Overactive Bladder**

**Definition**
• a symptom complex that includes urinary urgency with or without urgency incontinence, urinary frequency (voiding >8 times in a 24 hr period), and nocturia (awakening two or more times at night to void)

**Etiology**
• etiology unknown
• symptoms usually associated with involuntary contractions of the detrusor muscle. The overactivity of the muscle could be neurogenic, myogenic or idiopathic

**Epidemiology**
• F:M= 1:1
• prevalence increases with age. 42% in males 75 years old or older; 31% in females 75 years old or older

**Diagnosis**
• the diagnostic process should document symptoms and signs that define overactive bladder and exclude other disorders that could cause of the patient’s symptoms
• minimal requirements for the process consist of
  ▪ focused history including past genitourinary disorders and conditions outlined in Table 8, questionnaires of LUTS for women and diaries of urination frequency, volume and pattern
  ▪ P/E including genitourinary, pelvic and rectal examination
  ▪ urinalysis to rule out hematuria and infection
  ▪ in some patients, the following investigations could be considered
    ▪ bladder scan for residual urine in patients with risk factors of urinary retention
    ▪ cystoscopy to rule out recurrent infections, carcinoma in situ and other intravesical abnormalities
    ▪ urodynamics to rule out obstruction in older men
Treatment

- **non-pharmacological**: behaviour therapies such as bladder training, bladder control strategies, pelvic floor muscle training, fluid management, and avoidance of caffeine
- **pharmacological**
  - anti-muscarinics such as oxybutinin hydrochloride, tolterodine, solifenacin, fesoterodine, or trospium
  - β3-adrenoceptor agonist such as mirabegron
- refractory patients may be treated with
  - neuromuscular-junction inhibition such as botulinum toxin bladder injection
- other interventional procedures include
  - posterior tibial nerve stimulation (not used commonly in Canada)
  - sacral neuromodulation

Table 8. Conditions that could contribute to symptoms of Overactive Bladder

<table>
<thead>
<tr>
<th>Condition</th>
<th>UTI, obstruction, impaired bladder contractility</th>
<th>Stroke, MS, dementia, diabetic neuropathy</th>
<th>CHF, sleep disorders (primarily nocturia)</th>
<th>Excessive caffeine and alcohol, constipation, impaired mobility</th>
<th>Diuretics, anticholinergic agents, narcotics, calcium-channel blocker, cholinesterase inhibitors</th>

</table>

Antibiotic therapy should always be based on local resistance patterns and adjusted according to culture and sensitivity results.

Cystitis: Common Pathogens

**KEEPS**
- Klebsiella sp.
- E. coli (90%), other Gram-negatives
- Enterococci
- Proteus mirabilis, Pseudomonas
- S. saprophyticus

Acute uncomplicated pyelonephritis: suspected or confirmed enterococcus infection requires treatment with ampicillin.
Urinary Tract Infection

- for UTIs during pregnancy, see Obstetrics, OB29

**Definition**
- symptoms suggestive of UTI + evidence of pyuria and bacteriuria on U/A or urine C&S
  - if asymptomatic + 100,000 CFU/mL = asymptomatic bacteriuria; only requires treatment in certain patients (e.g. pregnancy)

**Classification**
- uncomplicated: lower UTI in a setting of functionally and structurally normal urinary tract
- complicated: structural and/or functional abnormality, male patients, immunocompromised, diabetic, iatrogenic complication, pregnancy, pyelonephritis, catheter-associated
- recurrent: see Recurrent/Chronic Cystitis

**Risk Factors**
- stasis and obstruction
  - residual urine due to impaired urine flow e.g. PUVs, reflux, medication, BPH, urethral stricture, cystocele, neurogenic bladder
- foreign body
  - introduce pathogen or act as nidus of infection e.g. catheter, instrumentation
- decreased resistance to organisms
  - DM, malignancy, immunosuppression, spermicide use, estrogen depletion, antimicrobial use
- other factors
  - trauma, anatomic abnormalities, female, sexual activity, fecal incontinence

**Clinical Features**
- storage symptoms: frequency, urgency, dysuria
- voiding symptoms: hesitancy, post-void dribbling
- other: suprapubic pain, hematuria, foul-smelling urine
- pyelonephritis – if present: typically presents with more severe symptoms (e.g. fever/chills, CVA tenderness, flank pain)

**Organisms**
- typical organisms
- atypical organisms
  - tuberculosis (TB)
  - *Chlamydia trachomatis*
  - Mycoplasma (*Ureaplasma urealyticum*)
  - fungi (Candida)

**Indications for Investigations**
- pyelonephritis
- persistence of pyuria/symptoms following adequate antibiotic therapy
- severe infection with an increase in Cr
- recurrent/persistent infections
- atypical pathogens (urea splitting organisms)
- Hx of structural abnormalities/decreased flow

**Investigations**
- U/A, urine C&S
  - UA: leukocytes ± nitrites ± hematuria
  - C&S: midstream, catheterized, or suprapubic aspirate
- if hematuria present, retest post-treatment, if persistent need hematuria workup (see Microscopic Hematuria, US)
- U/S, CT scan if indicated

**Treatment**
- see Table 8 for approach to ABx therapy
- if febrile, consider admission with IV therapy and rule out obstruction

**Prevention of UTIs**
- Maintain good hydration (try cranberry juice)
- Wipe from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse
Recurrent/Chronic Cystitis

Definition
• ≥3 UTIs/yr

Etiology
• bacterial reinfection (80%) vs. bacterial persistence (relapse)
  ▪ bacterial reinfection
    • recurrence of infection with either 1) a different organism, 2) the same organism if cultured >2 wk following therapy, or 3) with any organism with an intermittent sterile culture
  ▪ bacterial persistence
    • same organism cultured within 2 wk of sensitivity-based therapy

Investigations
• assess predisposing factors as described above
• investigations may include cystoscopy, U/S, CT

Treatment
• lifestyle changes (limit caffeine intake, increase fluid/H2O intake)
• ABx: continuous vs. post-coital
• post-menopausal women: consider topical or systemic estrogen therapy
• no treatment for asymptomatic bacteriuria except in pregnant women or patients undergoing urinary tract instrumentation

Interstitial Cystitis
(Painful Bladder or Bladder Pain Syndrome)

Definition
• bladder pain, chronic urgency and frequency without other reasonable causation

Classification
• non-ulcerative (more common)
• ulcerative

Etiology
• unknown
  ▪ theories: increased epithelial permeability, autoimmune, neurogenic, defective GAG layer overlying mucosa
  ▪ associations: severe allergies, IBS, fibromyalgia

Epidemiology
• prevalence: 20/100,000
• 90% of cases are in females
• mean age at onset is 40 yr (non-ulcerative tends to affect a younger to middle-aged population, while ulcerative tends to be seen in middle-aged to older)

Clinical Features
• pain associated with the bladder
• glomerulations (submucosal petechiae) or Hunner’s lesions (ulcers) on cystoscopic examination
• urinary urgency
• negative U/A, urine C&S, and urine cytology

Differential Diagnosis
• UTI, vaginitis, bladder tumour
• radiation/chemical cystitis
• eosinophilic/TB cystitis
• bladder calculi

Treatment
• first-line: patient empowerment (diet, lifestyle, stress management), pain management
• second-line
  ▪ oral: pentosan polysulfate sodium, amitriptyline, cimetidine, hydroxyzine
  ▪ intravesical: dimethylsulfoxide (DMSO), heparin, lidocaine
• third-line: cystoscopy with bladder hydrodistention (traditionally diagnostic) under GA, treat Hunner’s lesions if present
• other: neuromodulation, cyclosporine A, intradetrusor botulinum toxin
• surgery (last resort): augmentation cystoplasty, or urinary diversion ± cystectomy

Four Symptom Scores Exist to Evaluate and Monitor Patients with Interstitial Cystitis
• Interstitial Cystitis Symptom Index (ICSI)
• Interstitial Cystitis Problem Index (ICPI)
• Wisconsin Interstitial Cystitis (UW-IC) Scale
• Pain, Urgency and Frequency (PUF) Score

Cystoscopic evaluation is not necessary to make a diagnosis
**Acute Pyelonephritis**

**Definition**
- infection of the renal parenchyma with local and systemic manifestations
- clinical diagnosis of flank pain, fever and elevated WBC

**Etiology**
- ascending (usually GN bacilli) or hematogenous route (usually GP cocci)
- causative microorganisms
  - gram positives: *Enterococcus faecalis, S. aureus, S. saprophyticus*
  - gram negatives: *E. coli* (most common), *Klebsiella, Proteus, Pseudomonas, Enterobacter*
- common underlying causes of pyelonephritis
  - stones, strictures, prostatic obstruction, vesicoureteric reflux, neurogenic bladder, catheters, DM, sickle-cell disease, PCKD, immunosuppression, post-renal transplant, instrumentation, pregnancy

**Clinical Features**
- rapid onset (<24 h)
- LUTS including frequency, urgency, hematuria; NOT dysuria unless concurrent cystitis
- fever, chills, nausea, vomiting, myalgia, malaise
- CVA tenderness or exquisite flank pain

**Investigations**
- U/A, urine C&S
- CBC and differential: leukocytosis, left shift
- imaging indicated if suspicious of complicated pyelonephritis or symptoms do not improve with 48-72 h of treatment
  - abdominal/pelvic U/S
  - CT
- nuclear medicine: DMSA scan can be used to help secure the diagnosis
  - a photopenic defect indicates active infection or scar; if normal alternative diagnoses should be considered

**Treatment**
- hemodynamically stable
  - outpatient oral ABx treatment ± single initial IV dose (see Table 9)
- severe or non-resolving
  - admit, hydrate, and treat with IV ABx (see Table 9)
- emphysematous pyelonephritis
  - percutaneous nephrostomy tube and antibiotics first line
  - consider early nephrectomy after IV ABx started and patient stabilized
- renal obstruction
  - admit for emergent stenting or percutaneous nephrostomy tube

**Prostatitis/Prostatodynia**

**Epidemiology**
- most common urologic diagnosis in men <50 yr
- prevalence 2-12%

---

Nitrofurantoin has poor tissue penetration and therefore is not used to treat pyelonephritis (requires post-renal uroconcentration)
### Classification

#### Table 10. Comparison of the Three Types of Prostatitis

<table>
<thead>

</tbody>
</table>

Treatment
See Table 9

Stone Disease

Epidemiology
• prevalence of 2-3%
• M:F = 3:1
• peak incidence 30-50 yr of age
• recurrence rate: 10% at 1 yr, 50% at 5 yr, 60-80% lifetime

Risk Factors
• hereditary: RTA, Glucose-6-phosphate dehydrogenase deficiency, cystinuria, xanthinuria, oxaluria, etc.
• lifestyle: minimal fluid intake; excess vitamin C, oxalate, purines, calcium
• medications: loop diuretics (furosemide, bumetanide), acetazolamide, topiramate, and zonisamide
• medical conditions: UTI (with urea-splitting organisms: Proteus, Pseudomonas, Providencia, Klebsiella, Mycoplasma, Serratia, S. aureus), myeloproliferative disorders, IBD, gout, DM, hypercalcemia disorders (hyperparathyroidism, tumour lysis syndrome, sarcoidosis, histoplasmosis), obesity (BMI >30)

Clinical Features
• urinary obstruction → upstream distention → pain
  ▪ flank pain from renal capsule distention (non-colicky)
  ▪ severe waxing and waning pain radiating from flank to groin, testis, or tip of penis due to stretching of collecting system or ureter (ureteral colic)
• writhing, never comfortable, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
• occasionally symptoms of trigonal irritation (frequency, urgency)
• bladder stones result in: storage and voiding LUTS, terminal hematuria, suprapubic pain
• if fever, rule out concurrent pyelonephritis and/or obstruction

<td>Pancreatitis</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Other acute abdominal crisis</td>
<td></td>
</tr>
</tbody>
</table>

Location of Stones
• calyx: may cause flank discomfort, persistent infection, persistent hematuria, or remain asymptomatic
• pelvis: tend to cause obstruction at UPJ, may cause persistent infection
• ureter: <5 mm diameter will pass spontaneously in 75% of patients

Stone Pathogenesis
• supersaturation of stone constituents (at appropriate temperature and pH)
• stasis, low flow, and low volume of urine (dehydration)
• crystal formation and stone nidus
• loss of inhibitory factors
  ▪ citrate (forms soluble complex with calcium)
  ▪ magnesium (forms soluble complex with oxalate)
  ▪ pyrophosphate
  ▪ Tamm-Horsfall glycoprotein

**Who gets it?**
- Everyone
- Most
- First episode renal colic
- Pediatric cases or those concerning for obstruction
- ± Those concerning for bladder stone
- Recurrent Ca²⁺ stone formers
- ± pediatric cases

**Why is it done?**
- May show signs of infection, ± sensitivities
- 90% of stones are radiopaque, Good for follow-up
- Distinguish radiolucent stone from soft tissue filling defect X-ray comparison
- Identify and follow-up stone without radiation exposure Visualize hydronephrosis
- Visualize bladder Need to rule out metabolic cause for stones

**Cautions**
- – Do not mistake phleboliths for stones!
- Radiation (especially if female of child bearing age) Must be a non-contrast scan
- Not good at visualizing stones in ureter
- – –

- Radiation (especially if female of child bearing age) Must be a non-contrast scan
- Not good at visualizing stones in ureter
- – –

### Treatment – Acute

- **Medical**
  - analgesic ± antiemetic
  - NSAIDs help lower intra-ureteral pressure
  - medical expulsion therapy (MET)
  - α-blockers: increase rate of spontaneous passage in distal ureteral stones
  - calcium channel blockers
  - ± Abx for bacteriuria
  - IV fluids if vomiting (note: IV fluids do NOT promote stone passage)
- **Interventional**
  - required if obstruction endangers patient, e.g. sepsis, renal failure
  - first line: ureteric stent (via cystoscopy)
  - second line: image-guided percutaneous nephrostomy
- admit if necessary
  - **Indications for Admission to Hospital**

### Treatment – Elective

- **Medical**
  - likely conservative if ureteral stone <10 mm or kidney stone <5 mm and no complications/symptoms well controlled
  - stones <5 mm especially likely to pass spontaneously
  - PO fluids to increase urine volume to >2 L/d (3-4 L if cystine) and MET
  - specific to stone type (see Table 14)
  - periodic imaging to monitor stone position and assess for hydronephrosis
  - progress to interventional stone removal methods if symptoms worsen or fail to improve (indicating stone passage)

**Indications for Admission to Hospital**
- Intractable pain
- Intractable vomiting
- Fever (suggests infection)
- Compromised renal function (including single kidney, bilateral obstructing stone)
- Pregnancy

**Detailed metabolic studies are NOT recommended unless complex patient (recurrent stone formers, pregnancy, pediatrics, strong family Hx, underlying kidney or systemic disease, etc.)**
• interventional
  • kidney
    - may stent prior to ESWL if stone is 1.5-2.5 cm
    - ESWL if stone <2 cm
    - PCNL if stone >2 cm
  • ureteral stones >10 mm
  • ESWL and URS are both first line treatment modalities for all locations
    - URS has significantly greater stone-free rates for stones at all locations in ureter, but also has higher complication rates (ureter perforation, stricture formation, etc.)
  • PCNL is second line treatment
  • laparoscopic or open stone removal (very rare)
  • bladder
    - transurethral stone removal or cystolitholapaxy
    - remove outflow obstruction (TURP or stricture dilatation)

Prevention
• dietary modification
  - increase fluid (>2 L/d), K+ intake
  - reduce animal protein, oxalate, Na+, sucrose, and fructose intake
  - avoid high-dose vitamin C supplements
  - thiazide diuretics for hypercalciuria
  - allopurinol for hyperuricosuria
  - potassium citrate for hypocitraturia, hyperuricosuria

</tbody>
</table>

Note:
- E. coli positive urine dip and cultures if stone >10mm confirmed by imaging.
- Autosomal recessive defect in small bowel mucosal absorption and renal tubular absorption of dibasic amino acids results in “COLA” in urine (cystine, ornithine, lysine, arginine).
- Aggressive stone disease seen in children and young adults.
- Recurrent stone formation, family Hx.
- Often staghorn calculi.
- Faintly radiopaque on KUB.
- Positive urine sodium nitroprusside test, urine chromatography for cystine.

Purpose: To determine whether or not alpha blockers compared with other pharmacological treatments or placebo improve stone clearance rates and other clinically relevant outcomes in patients presenting with symptoms of stones less than 10 mm confirmed by imaging.

Results/Conclusions: 32,197 yrs, 5,964 participants. Although patients using alpha-blockers were more likely to experience adverse effects compared to standard therapy, stone-free rates were significantly higher in the alpha-blocker group (RR 1.49, 95% CI 1.33-1.64), expulsion time was 2.91 days shorter, and there was a reduction in the number of pain episodes (MD -0.48, 95% CI -0.94 to -0.01), the need for analgesic medication (MD -38.17, 95% CI -74.93 to -1.41), and hospitalization (RR 0.35, 95% CI 0.13-0.97). Alpha blockers should therefore be offered as a primary treatment modality for ureteral stones.
Urological Neoplasms

Approach to Renal Mass

Figure 9. Workup of a renal mass
*Imaging modality may be different in cases of contrast allergy or elevated creatinine

Benign Renal Neoplasms

CYSTIC KIDNEY DISEASE

- **simple cysts**: usually solitary or unilateral
  - very common: up to 50% at age 50
  - usually incidental finding on abdominal imaging
  - **Bosniak Classification** is used to stratify for risk of malignancy based on cyst features from contrast CT
- **polycystic kidney disease**
  - autosomal recessive: multiple bilateral cysts, often leading to early renal failure in infants
  - autosomal dominant: progressive bilateral disease leading to HTN and renal failure, adult-onset
- **medullary sponge kidney**: cystic dilatation of the collecting ducts
  - usually benign course, but patients are predisposed to stone disease
- **von Hippel-Lindau syndrome**: multiple bilateral cysts or clear cell carcinomas (50% incidence of RCC)
  - renal cysts, cerebellar, spinal and retinal hemangioblastomas, pancreatic and epididymal cysts, pheochromocytomas

</tbody>
</table>

Malignant Renal Neoplasms

RENAAL CELL CARCINOMA

Etiology
- cause unknown
- originates from proximal convoluted tubule epithelial cells in clear cell subtype (most common)
- hereditary forms seen with von Hippel-Lindau syndrome and hereditary papillary renal carcinoma

Epidemiology
- 8th most common malignancy (accounts for 3% of all newly diagnosed cancers)
- 85% of primary malignant tumours in kidney
- M:F = 3:2
- peak incidence at 50-60 yr of age

Pathology
- histological subtypes: clear cell (75-85%), papillary (10-15%), chromophobic (5-10%), collecting duct
- sarcomatoid elements in any subtype is a poor prognostic factor

Risk Factors
- top 3 risk factors: smoking, HTN, obesity
- miscellaneous: horseshoe kidney, acquired renal cystic disease
- role of environmental exposures (aromatic hydrocarbons, etc.) remains an unproven risk factor for development of RCC

Clinical Features
- usually asymptomatic: frequently diagnosed incidentally by U/S or CT
- poor prognostic indicators: weight loss, weakness, anemia, bone pain
- classic “too late triad” found in 10-15%
  - gross hematuria 50%
  - flank pain <50%
  - palpable mass <30%
- was called the “internist’s tumour” because of paraneoplastic symptomatology – now called the “radiologist’s tumour” because of incidental diagnosis via imaging
- metastases: seen in 1/3rd of new cases; additional 20-40% will go on to develop metastases
  - bone, brain, lung and liver most common site
  - may invade renal veins and inferior vena cava lumen. This may result in ascites, hepatic dysfunction, right atrial tumour, and pulmonary emboli

Investigations
- routine labs for paraneoplastic syndromes (CBC, ESR, LFTs, extended electrolytes)
- U/A (60-75% have hematuria)
- renal U/S: solid vs. cystic lesion

RCC Systemic Effects: paraneoplastic syndromes (10-40% of patients)
- Hematopoietic disturbances: anemia, polycythemia, raised ESR
- Endocrinopathies: hypercalcemia (increased vitamin D hydroxylation), erythrocytosis (increased erythropoietin), HTN (increased renin), production of other hormones (prolactin, gonadotropins, TSH, insulin, and cortisol)
- Hepatic cell dysfunction or Stauffer syndrome: abnormal LFTs, decreased WBC count, fever, areas of hepatic necrosis; no evidence of metastases; reversible following removal of primary tumour
- Hemodynamic alterations: systolic HTN (due to AV shunting), peripheral edema (due to caval obstruction)
• contrast-enhanced CT: higher sensitivity than U/S for detection of renal masses and for staging purposes
• MRI: useful for evaluation of vascular extension
• renal biopsy: to confirm diagnosis if considering observation or other non-surgical therapy

Staging
• involves CT, CXR, liver enzymes and LFTs, bone/head imaging (if symptoms dictate)

Table 17. 2010 TNM Classification of Renal Cell Carcinoma

<table>
<thead>
<tr>
<th>T</th>
<th>N</th>
<th>M</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1: tumour &lt; 7 cm, confined to renal parenchyma</td>
<td>N0: no regional nodes</td>
<td>M0: no evidence of metastasis</td>

<td></td>
<td></td>
</tr>
<tr>
<td>T4: tumour extends beyond Gerota’s fascia including extension into ipsilateral adrenal</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Treatment
• surgical
  • radical nephrectomy: en bloc removal of kidney, tumour, ipsilateral adrenal gland (in upper pole tumours) and intact Gerota’s capsule and paraaortic lymphadenectomy
  • partial nephrectomy (parenchyma-sparing): small tumour (roughly <4 cm) or solitary kidney/bilateral tumours
  • surgical removal of solitary metastasis may be considered
  • ablative techniques (cryoablation, RFA)
  • palliative radiation to painful bony lesions
  • therapy for advanced stage
    • tyrosine kinase inhibitors for metastatic disease (e.g. sunitinib, sorafenib)
    • anti-angiogenesis/anti-VEGF (e.g. bevacizumab)
    • mTOR inhibitors (e.g. temsirolimus, everolimus)
    • high-dose IL-2 (high toxicity but able to induce long-term cure in 5-7% of patients)
    • IFN α: monotherapy has been largely replaced by molecularly targeted agents listed above

Prognosis
• stage at diagnosis most important prognostic factor
  • T1: 90-100% 5 yr survival
  • T2-T3: 60% 5 yr survival
  • metastatic disease: <5% 10 yr survival

Carcinoma of the Renal Pelvis and Ureter

Etiology
• risk factors include
  • smoking
  • chemicals/dietary exposures (industrial dyes and solvents; aristolochic acid)
  • analgesic abuse (acetaminophen, ASA, and phenacetin)
  • Balkan nephropathy

Epidemiology
• rare: accounts for 5% of all urothelial cancers
• frequently multifocal, 2-5% are bilateral
• M:F = 3:1
• relative incidence: bladder:renal:ureter = 100:1:1

Pathology
• 85% are papillary urothelial cell carcinoma; others include SCC and adenocarcinoma
• UCC of ureter and renal pelvis are histologically similar to bladder UCC

Clinical Features
• gross/microscopic hematuria
• flank pain
• storage or voiding symptoms (dysuria only if lower urinary tract involved)
• flank mass ± hydronephrosis (10-20%)
Investigations
- IVP/CT urogram
- cystoscopy and retrograde pyelogram

Treatment
- radical nephroureterectomy with cuff of bladder
- distal ureterectomy for distal ureteral tumours
- emerging role for endoscopic laser ablation in patients with low grade disease, poor baseline renal health

Bladder Carcinoma

Etiology
- unknown, but environmental risk factors include
  - smoking (main factor – implicated in 60% of new cases)
  - aromatic amines: naphthylamines, benzidine, tryptophan, phenacetin metabolites
  - cyclophosphamide
  - prior Hx of radiation treatment to the pelvis
  - Schistosoma hematobium infection (associated with SCC)
  - chronic irritation: cystitis, chronic catheterization, bladder stones (associated with SCC)
  - aristolochic acid: associated with Balkan Nephropathy (renal failure, upper tract urothelial cancer) and Chinese Herbal Nephropathy

Epidemiology
- 2nd most common urological malignancy
- M:F = 3:1, more common among whites than blacks
- mean age at diagnosis is 65 yr

Pathology
- classification
  - UCC >90%
  - SCC 5-7%
  - adenosquamous carcinoma 1%
  - others <1%
- stages and prognoses of urothelial carcinoma at diagnosis
  - non-muscle invasive (75%) ➔ >80% overall survival
    - 15% of these will progress to invasive UCC
  - the majority of these patients will have recurrence
  - invasive (25%) ➔ 50-60% 5 yr survival
    - 85% have no prior Hx of superficial UCC (i.e. de novo)
    - 50% have occult metastases at diagnosis, and most of these will develop overt clinical evidence of metastases within 1 yr – lymph nodes, lung, peritoneum, liver
- carcinoma in situ ➔ flat, non-papillary erythematous lesion characterized by dysplasia confined to urothelium
  - more aggressive, worse prognosis
  - usually multifocal
  - may progress to invasive UCC

Clinical Features
- asymptomatic (20%)
- hematuria (key symptom: 85-90% at the time of diagnosis)
- pain (50%) ➔ location determined by size/extent of tumour (i.e. flank, suprapubic, perineal, abdominal, etc.)
- clot retention (17%)
- storage urinary symptoms ➔ consider carcinoma in situ
- palpable mass on bimanual exam ➔ likely muscle invasion
- obstruction of ureters ➔ hydronephrosis and uremia (nausea, vomiting, and diarrhea)

Investigations
- U/A, urine C&S, urine cytology
- U/S
- CT scan with contrast ➔ look for filling defect
- cystoscopy with biopsy (gold standard)
- biopsy to establish diagnosis and to determine depth of penetration
- specific bladder tumour markers (e.g. NMP-22, BTA, Immunocyt, FDP)

Grading
- low grade: <=10% invasive, 60% recur
- high grade: 50-80% are invasive or should progress to invasive over time

Staging
- for invasive disease: CT or MRI, CXR, LFTs, extended electrolytes (Ca²⁺, Mg²⁺, PO₄³⁻) (metastatic workup)

</table>

### Figure 11. Urothelial carcinoma of bladder

**Treatment**
- superficial (non-muscle invasive) disease: Tis, Ta, T1
  - low-grade disease
  - single dose mitomycin c within 24 hours of resection reduces recurrence rates
  - TURBT ± intravesical chemo/immuno-therapy (e.g. BCG, mitomycin C) to decrease recurrence rate
  - maintenance with intravesical chemotherapy with BCG for 3 cycles every 3 mo, may be continued for 2-3 yr
- invasive disease: T2a, T2b, T3
  - radical cystectomy + pelvic lymphadenectomy with urinary diversion (e.g. ileal conduit, Indiana pouch, ileal neobladder) or TURBT + chemo-radiation (bladder sparing) for small tumours with non-obstructed ureters
  - neo-adjuvant chemotherapy prior to cystectomy may also be done
  - use of adjuvant chemotherapy after definitive local treatment is controversial
- advanced/metastatic disease: T4a, T4b, N+, M+
  - initial combination of systemic chemotherapy ± irradiation ± surgery

### Prognosis
- depends on stage, grade, size, number of lesions, recurrence and presence of CIS
  - T1: 90% 5 yr survival
  - T2: 55% 5 yr survival
  - T3: 20% 5 yr survival
  - T4/N+/M+: <5% 5 yr survival

**Prostate Cancer**

### Etiology
- not known
- risk factors
  - increased incidence in persons of African descent
  - high dietary fat = 2x risk

**Figure 12. Ileal conduit, Indiana pouch, ileal neobladder**

### Neoadjuvant Chemotherapy plus Cystectomy Compared with Cystectomy Alone for Locally Advanced Bladder Cancer

**NEJM 2003;349:859-866**

**Study:** Randomized clinical trial.
**Patients:** 317 patients with transitional-cell carcinoma of the bladder (T2NM0 to T4aN0M0).
**Intervention:** Randomized to undergo radical cystectomy or to receive three cycles of combined chemotherapy (methotrexate, vinblastine, doxorubicin, and cisplatin) followed by radical cystectomy.
**Main Outcome:** Survival. Secondary objective was to quantify down-staging of tumour following chemotherapy.
**Results:** At 5 yr after treatment initiation, 57% of the combination-therapy group vs. 43% of the cystectomy group were alive (p = 0.06). In the combination-therapy group, 38% of the patients were pathologically free of cancer at the time of cystectomy vs. 15% of the cystectomy-only group at the time of surgery (p < 0.001).
**Conclusions:** For locally advanced bladder carcinoma, neoadjuvant chemotherapy significantly reduces tumour volume and also improves survival.
• family Hx
  • 1st degree relative = 2x risk
  • 1st and 2nd degree relatives = 9x risk

Epidemiology
• most prevalent cancer in males
• 3rd leading cause of male cancer deaths (following lung and colon)
• up to 50% risk of CaP at age 50
• lifetime risk of death from CaP is 3%
• 75% diagnosed between ages of 60 and 85; mean age at diagnosis is 72

Pathology
• adenocarcinoma
  • >95%, often multifocal
• urothelial carcinoma of the prostate (4.5%)
  • associated with UCC of bladder; does NOT follow TNM staging below; not hormone-responsive
• endometrial (rare)
  • carcinoma of the utricle

Anatomy (see Figure 7, U7)
• 60-70% of nodules arise in the peripheral zone
• 10-20% arise in the transition zone
• 5-10% arise in the central zone

Clinical Features
• usually asymptomatic
• most commonly detected by DRE, elevated PSA, or as an incidental finding on TURP
  • DRE: hard irregular nodule or diffuse dense induration involving one or both lobes
  • PSA: see Prostate Cancer Screening, U26
• locally advanced disease
  • storage and voiding symptoms, ED (all uncommon without spread)
• metastatic disease
  • bony metastases to axial skeleton common
  • visceral metastases are less common (liver, lung, and adrenal gland most common sites)
  • leg pain and edema with nodal metastases obstructing lymphatic and venous drainage

Methods of Spread
• local invasion
• lymphatic spread to regional nodes
  • obturator > iliac > presacral/para-aortic
• hematogenous dissemination occurs early

Investigations
• DRE
• PSA elevated in the majority of patients with CaP
• TRUS-guided needle biopsy
• bone scan may be omitted in untreated CaP with PSA <10 ng/mL
• CT scanning to assess metastases
• MRI: being investigated for possible role in detection, staging, MRI-guided biopsying and active surveillance

</tbody>
</table>

Treatment
- T1/T2 (localized, low-risk)
  - if adequate life expectancy or no other significant comorbidities, consider active surveillance vs. definitive local treatment (RP, brachytherapy, or EBRT)
  - no difference in cure rate between definitive treatment modalities
- in older population: watchful waiting + palliative treatment for symptomatic progression
- T1/T2 (intermediate or high-risk)
  - definitive therapy over active surveillance
- T3, T4
  - EBRT + androgen deprivation therapy or RP + adjuvant EBRT
- N >0 or M >0
  - requires hormonal therapy/palliative radiotherapy for metastases; may consider combined androgen blockade
  - bilateral orchectomy – removes 90% of testosterone
  - GnRH agonists (e.g. leuprolide, goserelin)
  - GnRH antagonist (e.g. degarelix)
  - estrogens (e.g. diethylstilbestrol [DES])
  - antiandrogens (e.g. bicalutamide)
  - local irradiation of painful secondary or half-body irradiation
- hormone-refractory prostate cancer
  - chemotherapy: docetaxel, cabazitaxel, sipuleucel-T

<table>
<thead>
<tr>
<th>Modality</th>
<th>Population Considered</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Watchful Waiting</td>
<td>Short life expectancy (&lt;5-10 yr); will likely only receive non-curative hormonal therapy if disease progresses</td>
<td>Disease progression</td>
</tr>
<tr>
<td>Active Surveillance (serial PSA, DRE, and biopsies)</td>
<td>Low grade disease, good follow-up; is still considering more curative treatment if disease progresses</td>
<td>Disease progression; decrease in QOL associated with serial testing; risks associated with biopsies; no optimal monitoring schedule has been defined to date</td>
</tr>
<tr>
<td>Brachytherapy</td>
<td>Low volume, low PSA (&lt;10), low grade</td>
<td>Radiation proctitis (5%), ED (50%), risk of rectal cancer</td>
</tr>
<tr>
<td>EBRT</td>
<td>Locally advanced disease, older patients</td>
<td>Radiation proctitis (5%), ED (50%), risk of rectal cancer</td>
</tr>
<tr>
<td>RP</td>
<td>Young patients (&lt;75 yr), high-risk disease</td>
<td>Incontinence (10%), ED (30-50%)</td>
</tr>
</tbody>
</table>

*Other options include cryoablation, HIFU, hormonal ablation

Prognosis
- T1-T2: comparable to normal life expectancy
- T3-T4: 40-70% 10-yr survival
- N+ and/or M+: 4 % 5 yr survival
- prognostic factors: tumour stage, tumour grade, PSA value, PSA doubling time

Prostate Cancer Screening

Digital Rectal Exam
- should be included as part of initial screening
- suspicious findings: abnormal feeling, nodularity, focal lesion, discrete change in texture/fullness/symmetry

Prostate Specific Antigen
- glycoprotein produced by epithelial cells of prostate gland
- leaks into circulation in setting of disrupted glandular architecture
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic value, but no single justifiable cutpoint
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- PSA velocity, PSA density, and free:total PSA: all intended to increase sensitivity and specificity of serum PSA values
  - association of increased CaP rates with decreased free are total PSA, elevated PSA velocity and density

Screening Recommendations
- conflicting evidence regarding mortality reduction with PSA-based screening and debate regarding overdiagnosis/oftreatment

Radical Prostatectomy vs. Watchful Waiting in Early Prostate Cancer (Scandinavian Prostate Cancer Group Study)
- Methods: 731 men at 52 United States centres with localized prostate cancer participated.
- Results: For men with low-risk prostate cancer (PSA<10, Gleason score<7), at 15 yr after treatment initiation, the relative risk of death due to prostate cancer in the radical prostatectomy group versus watchful waiting was 0.62 (p=0.01). The cumulative incidence of death from prostate cancer after radical prostatectomy was as compared with other studies.
- Conclusions: Radical prostatectomy was associated with increased rate of death due to prostate cancer.

Radical Prostatectomy vs. Observation for Localized Prostate Cancer (Prostate Cancer Intervention vs. Observation Trial [PIVOT] Study Group)
- Methods: 731 men at 52 United States centres with localized prostate cancer participated.
- Results: Radical prostatectomy did not reduce all-cause or prostate cancer mortality relative to observation (relative risk 0.80, p=0.09), through at least 12 yr of follow-up.
- Conclusions: Observation is recommended for localized prostate cancer, especially in men with low PSA and low-risk disease.

Causes of Increased PSA
- BPH, prostatectasis, prostatic ischemia/infarction, prostate biopsy/surgery, prostatic massage, acute urinary retention, urethral catheterization, cystoscopy, TRUS, strenuous exercise, perineal trauma, ejaculation, acute renal failure, coronary bypass graft, radiation therapy

PSA is specific to the PROSTATE, but NOT to prostate cancer
**Canadian Urological Association Guidelines (2011) re: CaP Screening**

- harms and benefits of PSA testing must be explained to the patient and an informed, shared decision to test must be established
- initial screening should include both serum PSA and DRE
- all men should be offered screening at age 50 if >10 yr life-expectancy
- high-risk individuals (family Hx of CaP or African ancestry) should be offered screening at age 40 if >10 yr life-expectancy
- standard has been annual screening, but q2-4yr screening acceptable
- no strict cutoff for when to biopsy. Decision to biopsy should be based on more than a single PSA value

*new guidelines under development, however, AUA guidelines recommend against universal routine PSA screening for CaP*
Staging
- Clinical: CXR (lung mets), markers for staging (β-hCG, AFP, LDH), CT abdomen/pelvis (retroperitoneal lymphadenopathy)
  - Stage I: disease limited to testis, epididymis, or spermatic cord
  - Stage II: disease limited to the retroperitoneal nodes
  - Stage III: disease metastatic to supradiaphragmatic nodal or visceral sites

<td>M1b: distant mets other than to regional lymph nodes and lung</td>
</tr>
</tbody>
</table>

Management
- orchiectomy through inguinal ligament for all stages
- consider sperm banking, testicular prosthesis
- adjuvant therapies

Prognosis
- 99% cured with stage I and II disease
- 70-80% complete remission with advanced disease

Penile Tumours

Epidemiology
- rare (<1% of cancer in males in U.S.)
- most common in 6th decade

Benign
- cyst, hemangioma, nevus, papilloma

Pre-Malignant
- balanitis xerotica obliterans, leukoplaikia, Buschke-Lowenstein tumour (large condyloma)

Pre-invasive Cancer
- carcinoma in situ
  - Bowen's disease → crusted, red plaques on the shaft
  - erythroplasia of Queyrat → velvet red, ulcerated plaques on the glans
  - treatment options: local excision, laser, radiation, topical 5-fluorouracil

Malignant
- risk factors
  - chronic inflammatory disease
  - STI
  - phimosis
  - uncircumcised penis
  - 2% of all urogenital cancers
  - SCC (>95%), basal cell, melanoma, Paget's disease of the penis (extremely rare)
  - definitive diagnosis requires full thickness biopsy of lesion
  - lymphatic spread (superficial/deep inguinal nodes → iliac nodes) >> hematogenous
Treatment
- wide surgical excision with tumour-free margins (dependent on extent and area of penile involvement) ± lymphadenectomy
- consider less aggressive treatment modalities in CIS (cryotherapy, laser therapy, etc.) if available

<td>A small bulge in the groin that may increase in size with Valsalva and disappear when lying down Can present as a swollen or enlarged scrotum Discomfort or sharp pain – especially when straining, lifting, or exercising</td>
</tr>
<tr>
<td>Investigations</td>
<td>P/E Valsava</td>
<td>P/E U/S to rule out tumour</td>
<td>U/S to rule out tumour</td>
<td>U/S with colour flow Doppler probe over testicular artery Decrease uptake on 99mTc-pertechnetate scintillation scan (doughnut sign)</td>
<td>Hx and P/E Invagination of the scrotum Valsalva</td>
</tr>
<tr>
<td>Treatment</td>
<td>Conservative Surgical ligation of testicular veins Percutaneous vein occlusion (balloon, sclerosing agents) Repair may improve sperm count/motility 50-75%</td>
<td>Conservative Avoid needle aspiration as it can lead to infection, reaccumulation and spilling of irritating sperm within scrotum Excise if symptomatic</td>
<td>Conservative Needle drainage Surgical</td>
<td>Emergency surgical exploration and bilateral orchiopexy Orchiectomy if poor prognosis</td>
<td>Surgical repair</td>
</tr>
</tbody>
</table>

### Varicocele Grading
- Grade 1: Palpable only with Valsalva manoeuvre
- Grade 2: Palpable without Valsalva
- Grade 3: Visible through scrotal skin

Suspect a Retroperitoneal Mass/Process in a Patient with a Varicocele if
- Acute onset
- Right sided (isolated)
- Palpable abdominal mass
- Does not reduce while supine

Indications for Treatment of Varicocele
- Impaired sperm quality or quantity
- Pain or dull ache affecting QOL
- Affected testis fails to grow in adolescents
- Cosmetic indications (especially in adolescents)
TORSION OF TESTICULAR APPENDIX

- twisting of testicular/epididymal vestigial appendix

Signs and Symptoms

- clinically similar to testicular torsion, but vertical lie and cremaster reflex preserved
- “blue dot sign”
  - blue infarcted appendage seen through scrotal skin (can usually be palpated as small, tender lump)

Treatment

- analgesia – most will subside over 5-7 d
- surgical exploration and excision if refractory pain

HEMATOCELE

- trauma with bleed into tunica vaginalis
- U/S helpful to exclude fracture of testis which requires surgical repair

Treatment

- ice packs, analgesics, surgical repair

Differential of a Benign Scrotal Mass

His Bits

- Hydrocele
- Infection (epididymitis/orchitis)
- Sperm (spermatocele)
- Blood (hematocele)
- Intestines (hernia)
- Torsion
- Some veins (varicocele)

Penile Complaints

</tbody>
</table>

Erectile Dysfunction

Definition

- consistent (>3 mo duration) or recurrent inability to obtain or maintain an adequate erection for satisfactory sexual performance

Physiology

- erection involves the coordination of psychologic, neurologic, hemodynamic, mechanical, and endocrine components
- nerves: sympathetic (T11-L2), parasympathetic (S2-4), somatic (dorsal penile/pudendal nerves [S2-4])
• erection ("POINT")
  - parasympathetics → release of nitric oxide (NO) → increased cGMP levels within corpora cavernosa leading to:
    1. arteriolar dilatation
    2. sinusoidal smooth muscle relaxation → increased arterial inflow and compression of penile venous drainage (decreased venous outflow)
• emission ("SHOOT")
  - sensory afferents from glans
  - secretions from prostate, seminal vesicles, and ejaculatory ducts enter prostatic urethra (sympathetics)
• ejaculation ("SHOOT")
  - bladder neck closure (sympathetic)
  - spasmodic contraction of bulbo-cavernosus and pelvic floor musculature (somatic)
• detumescence
  - sympathetic nerves, norepinephrine, endothelin-1 → arteriolar and sinusoidal constriction → penile flaccidity

</tr>
<tr>
<td>(HTN, DM, dyslipidemia)</td>
<td></td>
</tr>
<tr>
<td>Nocturnal/AM Erection</td>
<td>Present</td>
</tr>
</tbody>
</table>

Etiology ("IMPOTENCE")
• Iatrogenic: pelvic surgery, pelvic radiation
• Mechanical: Peyronie’s, priapism
• Psychological: depression, stress, anxiety, PTSD, widower syndrome
• Occlusive vascular: arterial HTN, DM, smoking, hyperlipidemia, PVD, venous (impaired veno-occlusion)
• Trauma: penile/pelvic, bicycling
• Extra factors: renal failure, cirrhosis, COPD, sleep apnea, malnutrition
• Neurogenic: CNS (e.g. Parkinson’s, MS, spinal cord injury, Guillain-Barré, spina bifida, stroke), PNS (e.g. DM, peripheral neuropathy)
• Chemical: antihypertensives, sedatives, antidepressants, antipsychotics, anxiolytics, antibiotics, antiandrogens (including 5-α reductase inhibitors), statins, GnRH agonists, illicit drugs
• Endocrine: DM, hypogonadism, hyperprolactinemia, hypo/ hyperthyroid

Diagnosis
• complete Hx (include sexual, medical, and psychosocial aspects)
• self-administered questionnaires (e.g. International Index of Erectile Function, Sexual Health Inventory for Men Questionnaire, ED Intensity Scale, ED Impact Scale)
• focused P/E, including vascular and neurologic examinations, secondary sexual characteristics
• lab investigations, dependent on clinical picture
  - risk factor evaluation: fasting blood glucose or HbA1c, cholesterol profile
  - optional: TSH, CBC, U/A, testosterone (free and total), prolactin, LH
• specialized testing including nocturnal penile tumescence monitoring usually unnecessary
• psychological/psychiatric assessment could be considered to rule out performance anxiety
• evaluation of penile vasculature only relevant with past history of trauma (i.e. pelvic fracture)

Treatment
• can often be managed by family doctor, see sidebar for when to refer
• must fully inform patient/partner of options, benefits and complications
• non-invasive
  - lifestyle changes (alcohol, smoking), psychological (sexual counseling and education)
  - change precipitating medications
  - treat underlying causes (DM, CVD, HTN, endocrinopathies)
• minimally invasive
  - oral medication (see Common Medications, U43)
    - sildenafil, tadalafil, vardenafil, avanafil: inhibits PDE-5 to increase intracavernosal cyclic GMP levels
      - all four have similar effectiveness, but tadalafil has certain advantages: earlier onset, longer half-life, no cyanopsia, can be taken on empty or full stomach (others better on empty stomach)
    - vacuum devices: draw blood into penis via negative pressure, then put ring at base of penis once erect
    - MUSE: male urethral suppository for erection – vasoactive substance (PGE1) capsule inserted into urethra
  - invasive
    - intracavernous vasodilator injection/self-injection
      - triple therapy (papaverine, phentolamine, PGE1) or PGE1 alone
      - complications: priapism (overdose), thickening of tunica albuginea at site of repeated injections (Peyronie’s plaque) and hematoma
  - surgical
    - penile implant (last resort): malleable or inflatable
    - penile artery reconstruction (in young men with isolated vascular lesion – investigational)

Trauma

• see Emergency Medicine, ER41

Renal Trauma

Classification According to Severity
• minor
  - contusions and superficial lacerations/hematomas: 90% of all blunt traumas, surgical exploration seldom necessary
• major
  - laceration that extends into medulla and collecting system, major renal vascular injury, shattered kidney

Etiology
• 80% blunt (MVC, assaults, falls) vs. 20% penetrating (stab wounds and gunshots)

Clinical Features
• mechanism of injury raises suspicion
• can be hemodynamically unstable secondary to renal vascular injury and/or other sustained injuries: ABCs
• upper abdominal tenderness, flank tenderness, flank contusions, lower rib/vertebral transverse process fracture

Investigations
• U/A
  - hematuria: requires workup but degree does not correlate with the severity of injury
• imaging
  - CT (contrast, triphasic) if patient stable: look for renal laceration, extravasation of contrast, retroperitoneal hematoma, and associated intra-abdominal organ injury

Staging (does not necessarily correlate well with clinical status)
• I: contusion/hematoma
• II: <1 cm laceration without urinary extravasation
• III: >1 cm laceration without urinary extravasation
• IV: urinary extravasation
• V: shattered kidney or avulsion of pedicle

Treatment
• microscopic hematuria + isolated well-staged minor injuries → no hospitalization
• gross hematuria + contusion/minor lacerations → hospitalize, bedrest, repeat CT if bleeding persists
• surgical intervention/minimally invasive angiography and embolization
  - absolute indications
    - hemorrhage and hemodynamic instability
relative indications
  • non-viable tissue and major laceration
  • urinary extravasation
  • vascular injury
  • expanding or pulsating peri-renal mass
  • laparotomy for associated injury
• follow-up with U/S or CT before discharge, and at 6 wk

Complications
• HTN in 5% of renal trauma

Bladder Trauma

Classification
• contusions: no urinary extravasation, damage to mucosa or muscularis
• intraperitoneal ruptures: often involve the bladder dome
• extraperitoneal ruptures: involve anterior or lateral bladder wall in full bladder

Etiology
• blunt (MVC, falls, and crush injury) vs. penetrating trauma to lower abdomen, pelvis, or perineum
• blunt trauma is associated with pelvic fracture in 97% of cases

Clinical Features
• abdominal tenderness, distention, peritonitis, and inability to void
• can be hemodynamically unstable secondary to pelvic fracture, other sustained injuries: ABCs
• suprapubic pain

Investigations
• U/A: gross hematuria in 90%
• imaging (including CT cystogram and post-drainage films for extravasation)

Treatment
• penetrating trauma → surgical exploration
• contusion → urethral catheter until hematuria completely resolves
• extraperitoneal bladder perforations → typically non-operative with foley insertion, and follow with cystograms
  ▪ surgery if: infected urine, rectal/vaginal perforation, bony spike into bladder, laparotomy for concurrent injury, bladder neck involvement, persistent urine leak and failed conservative management
• intraperitoneal rupture usually requires surgical repair and suprapubic catheterization

Complications
• complications of bladder injury itself are rare
• mortality is around 20%, and is usually due to associated injuries rather than bladder rupture

Urethral Injuries

Etiology
• posterior urethra
  ▪ common site of injury is junction of membranous and prostatic urethra due to blunt trauma, MVCs, pelvic fracture
  ▪ shearing force on fixed membranous and mobile prostatic urethra
• anterior urethra
  ▪ straddle injury can crush bulbar urethra against pubic rami
• other causes
  ▪ iatrogenic (instrumentation, prosthesis insertion), penile fracture, masturbation with urethral manipulation
• always look for associated bladder rupture

Clinical Features
• blood at urethral meatus
• high-riding prostate on DRE
• swelling and butterfly perineal hematoma
• penile and/or scrotal hematoma
• sensation of voiding without U/O
• distended bladder
Investigations
• must perform RUG or cystoscopy prior to catheterization

Treatment
• simple contusions
  ▫ no treatment
• partial urethral disruption
  ▫ very gentle attempt at catheterization by urologist
  ▫ with no resistance to catheterization → Foley x 2-3 wk
  ▫ with resistance to catheterization → suprapubic cystostomy or urethral catheter alignment in OR
• periodic flow rates/urethrograms to evaluate for stricture formation
• complete disruption
  ▫ immediate repair if patient stable, delayed repair if unstable (suprapubic tube in interim)

Complications
• stricture

Infertility

Definition
• failure to conceive after one year of unprotected, properly timed intercourse
• incidence
  ▫ 15% of all couples
  ▫ ~ 35-40% female, 20% male, 25-30% combined problem

Female Factors
• see Gynecology, GY23

Male Factors

Male Reproduction
• hypothalamic-pituitary-testicular axis (HPTA)
  ▫ pulsatile GnRH from hypothalamus acts on anterior pituitary stimulating release of LH and FSH
  ▫ LH acts on Leydig (interstitial) cells → testosterone synthesis and secretion
  ▫ FSH acts on Sertoli cells → structural and metabolic support to developing spermatogenic cells
  ▫ FSH and testosterone support germ cells (responsible for spermatogenesis)
  ▫ sperm route: epididymis → vas deferens → ejaculatory ducts → prostatic urethra

Etiology
• idiopathic (40-50% infertile males)
• testicular
  ▫ varicocele (35-40% infertile males)
  ▫ tumour
  ▫ congenital (Klinefelter’s triad: small, firm testes, gynecomastia, and azoospermia)
  ▫ post-infectious (epididymo-orchitis, STIs, mumps)
  ▫ uncorrected torsion
  ▫ cryptorchidism (<5% of cases)
• obstructive
  ▫ iatrogenic (surgery; see below)
  ▫ infectious (gonorrhea, chlamydia)
  ▫ trauma
  ▫ congenital (absence of vas deferens, CF)
  ▫ bilateral ejaculatory duct obstruction, epididymal obstructions
  ▫ Kartagener’s syndrome (autosomal recessive disorder causing defect in action of cilia)
• endocrine (see Endocrinology, E48)
  ▫ HPTA (2-3%) e.g. Kallmann’s syndrome (congenital hypothalamic hypogonadism), excess prolactin, excess androgens, excess estrogens
• other
  ▫ retrograde ejaculation secondary to surgery
  ▫ medications
  ▫ drugs: marijuana, cocaine, tobacco, alcohol
  ▫ increased testicular temperature (sauna, hot baths, tight pants or underwear)
  ▫ chronic disease: e.g. liver, renal
  ▫ unexplained infertility
History
- age of both partners
- medical: past illness, DM, trauma, CF, genetic syndromes, STIs, cryptorchidism
- surgical: vasectomy, herniorrhaphy, orchidopexy, prostate surgery
- fertility: pubertal onset, previous pregnancies, duration of infertility, treatments
- sexual: libido, erection/ejaculation, timing, frequency
- family Hx
- medications: cytotoxic agents, GnRH agonists, anabolic steroids, nitrofurantoin, cimetidine, sulfasalazine, spironolactone, α-blockers
- social Hx: alcohol, tobacco, cocaine, marijuana
- occupational exposures: radiation, heavy metals

Physical Exam
- general appearance: sexual development, gynecomastia, obesity
- scrotal exam: size, consistency, and nodularity of testicles; palpation of cord for presence of vas deferens; DRE; Valsalva for varicocele

Investigations
- semen analysis (SA) at least 2 specimens, collected 1-2 weeks apart
  - delivery to lab within 1 hour, 2-7 days of abstinence prior to collection
- hormonal evaluation
  - indicated with abnormal SA (rare to be abnormal with normal SA)
  - testosterone and FSH
  - serum LH and prolactin are measured if testosterone or FSH are abnormal
- genetic evaluation
  - chromosomal studies (Klinefelter’s syndrome – XXY)
  - genetic studies (Y-chromosome microdeletion, CF gene mutation)
- immunologic studies (antisperm antibodies in ejaculate and blood)
- testicular biopsy
- scrotal U/S (varicocele, testicular size)
- vasography (assess patency of vas deferens)

Treatment
- assessment of partner
- lifestyle
  - regular exercise, healthy diet
  - eliminate alcohol, tobacco and illicit drugs
- medical
  - endocrine therapy (see Endocrinology, E49)
  - treat retrograde ejaculation
  - discontinue anti-sympathomimetic agents, may start α-adrenergic stimulation
    (phenylpropanolamine, pseudoephedrine, or ephedrine)
  - treat underlying infections
- surgical
  - varicocelectomy (if indicated)
  - vasovasostomy (vasectomy reversal) or epididymovasostomy
  - transurethral resection of blocked ejaculatory ducts
- assisted reproductive technologies (ART)
  - refer to infertility specialist
  - sperm washing + intrauterine insemination (IUI)
  - in vitro fertilization (IVF)
  - intracytoplasmic sperm injection (ICSI) after CF screening of patient and partner in patients with congenital bilateral absence of vas deferens

Common Terminology on SA
- Teratospermia: Abnormal morphology
- Asthenospermia: Abnormal motility
- Oligospermia: Decreased sperm count
- Azoospermia: Absent sperm in semen
- Mixed types: i.e. oligoasthenospermia

Mutation of cystic fibrosis transmembrane conductance regulator (CFTR) gene is associated with congenital bilateral absence of vas deferens and epididymal cysts, even if patient manifests no symptoms of CF
Pediatric Urology

Congenital Abnormalities

- not uncommon; 1/200 have congenital abnormalities of the GU tract
- six common presentations of congenital urological abnormalities

1. ANTEnatal HYDRONEPHROSIS

Epidemiology
- 1-5% fetal U/S, detectable as early as first trimester
- most common urological consultation in perinatal period and one of most common U/S abnormalities of pregnancy

Differential Diagnosis
- UPJ or UVJ obstruction
- multi-cystic dysplastic kidney
- VUR
- PUVs (only in boys)
- duplication anomalies
- ureteroceles
- ectopic ureter

Treatment
- antenatal in utero intervention rarely indicated unless evidence of PUVs with oligohydramnios

2. POSTERIOR URETHRAL VALVES

Epidemiology
- the most common congenital obstructive urethral lesion in male infants

Pathophysiology
- abnormal mucosal folds at the distal prostatic urethra causing varying degrees of obstruction

Clinical Presentation
- dependent on age
  - antenatal: bilateral hydronephrosis, distended bladder, oligohydramnios
  - neonatal (recognized at birth): palpable abdominal mass (distended bladder, hydronephrosis), ascites (transudation of retroperitoneal urine), respiratory distress (pulmonary hypoplasia from oligohydramnios), weak urinary stream
  - neonatal (not recognized at birth): within weeks present with urosepsis, dehydration, electrolyte abnormalities, failure to thrive

WHO Guidelines

Normal Semen Values
- Volume: 2-5 mL
- Concentration: >15 million sperm/mL
- Morphology: 30% normal forms
- Motility: >40% adequate forward progression
- Liquefaction: complete in 20 min
- pH: 7.2-7.8
- WBC: <10/HPF or <10^6 WBC/mL semen

Majority of antenatal hydronephroses resolve during pregnancy or within the first year of life
- toddlers: UTIs or voiding dysfunction
- school-aged boys: voiding dysfunction → urinary incontinence
- associated findings include renal dysplasia and secondary VUR

**Investigations**
- most commonly recognized on prenatal U/S → bilateral hydronephrosis, thickened bladder, dilated posterior urethra ("keyhole sign"), oligohydramnios in a male fetus
- VCUG → dilated and elongated posterior urethra, trabeculated bladder, VUR

**Treatment**
- immediate catheterization to relieve obstruction, followed by cystoscopic resection of PUV when baby is stable
- if resection of PUV is not possible, vesicostomy is indicated

### 3. URETEROPELVIC JUNCTION OBSTRUCTION

**Etiology**
- unclear: adynamic ureteral segment, stenosis, strictures, extrinsic compression, stenosis, strictures, aberrant blood vessels
- can rarely be secondary to tumour, stone, etc, in children

**Epidemiology**
- the most common congenital defect of the ureter
- M:F = 2:1
- up to 40% bilateral, which may be associated with worse prognosis

**Clinical Presentation**
- symptoms depend on severity and age at diagnosis (mostly asymptomatic finding on antenatal U/S)
  - infants: abdominal mass, urinary infection
  - children: pain, vomiting, failure to thrive
- some cases are diagnosed after puberty and into adulthood
  - in adolescents and adults, the symptoms may be triggered by episodes of increased diuresis, such as following alcohol ingestion (Dietl's crisis)

**Investigations**
- antenatal U/S most common, Doppler U/S (rare), IVP (rare), and renal scan ± furosemide

**Treatment**
- surgical correction (pyeloplasty), consider nephrectomy if <15% differential renal function

### 4. VESICOURETERAL REFLUX

**Definition**
- retrograde passage of urine from the bladder, through the UVJ, into the ureter

**Classification**
- primary reflux: incompetent or inadequate closure of UVJ
  - lateral ureteral insertion, short submucosal segment
- secondary reflux: abnormally high intravesical pressure resulting in failure of UVJ closure
  - often associated with anatomic (PUV) or functional (neuropathic) bladder obstruction

**Epidemiology**
- estimated ~1% of newborns, but not well known
- incidence and clinical relevance higher in children with febrile UTIs and prenatal hydronephrosis
- risk factors: race (white > black), female gender, age (<2 yr), genetic predisposition

**Investigations**
- focused Hx, particularly of voiding dysfunction (frequency, urgency, diurnal enuresis, constipation, encopresis)
  - also screen for signs of infection (UTI, pyelonephritis, urosepsis) and renal failure (uremia, HTN)
- initial evaluation of renal status, growth parameters, and blood pressure is warranted in any child with VUR due to high incidence of renal scarring
  - height, weight, blood pressure
  - Cr
  - U/A, C&S
  - renal U/S
- DMSA renal scan if at high risk (greater sensitivity in detecting structural defects associated with dysplasia, renal scarring or pyelonephritis; entails radiation exposure)
- family screening is controversial
Treatment
• spontaneous resolution in 60% of primary reflux
  ▪ in lower grades (I-III), goal is to prevent infection or renal damage via medical treatment
  and monitoring
• medical treatment: daily ABx prophylaxis at half the treatment dose for acute infection (see Table 9 - TMP/SMX, trimethoprim, amoxicillin, or nitrofurantoin)
• surgical treatment: ureteral reimplantation ± ureteroplasty, or subureteral injection with bulking agents (DeFlux® or Macroplastique®)
  ▪ indications include failure of medical management, renal scarring (e.g. renal insufficiency, HTN), breakthrough UTIs, persistent high grade (IV or V) reflux

5. HYPOSPADIAS
Definition
• a condition in which the urethral meatus opens on the ventral side of the penis, proximal to the normal location in the glans penis
• depending on severity, may result in difficulty directing urinary stream, having intercourse or depositing sperm in vagina

Epidemiology
• very common; 1/300 live male births
• distal hypospadias more common than proximal
• white >> black
• may be associated with ventral penile curvature, disorders of sexual differentiation, undescended testicles or inguinal hernia

Treatment
• early surgical correction; optimal repair before 2 yr
• neonatal circumcision should be deferred because the foreskin may be utilized in the correction

6. EPISPADIAS-EXSTROPHY COMPLEX
Definition
• a spectrum of defects depending on the timing of the rupture of the cloacal membrane
  ▪ bladder extrophy: congenital absence of a portion of lower abdominal and anterior bladder wall, with exposure of the bladder lumen
  ▪ cloacal extrophy
    • exposed bladder and bowel with imperforate anus
    • associated with spina bifida in >50%
  ▪ epispadias (least severe)
    • urethra opens on dorsal aspect of the penis, often associated with penile curvature

Etiology
• represents failure of closure of the cloacal membrane, resulting in the bladder and urethra opening directly through the abdominal wall

Epidemiology
• rare: incidence 1/30,000, M:F = 3:1 predominance
• high morbidity → multiple reconstructive surgeries, incontinence, infertility, reflux

Treatment
• surgical correction at birth
• later corrections for incontinence, VUR, and low bladder capacity may be needed

Nephroblastoma (Wilms’ Tumour)
Etiology
• arises from abnormal proliferation of metanephric blastema

Epidemiology
• 5% of all childhood cancers, 5% bilateral
• most common primary malignant renal tumour of childhood
• average age of incidence is 3 yr
Clinical Features
- abdominal mass: large, firm, unilateral (80%)
- HTN (25%)
- flank tenderness
- microscopic hematuria
- nausea/vomiting

Treatment
- always investigate contralateral kidney and renal vein (for tumour thrombus)
- unilateral disease: radical nephrectomy ± radiation ± chemotherapy
- bilateral disease: nephron-sparing surgery following neoadjuvant chemotherapy

Prognosis
- 5 yr survival 80%

Cryptorchidism/Ectopic Testes

Definition
- abnormal location of testes somewhere along the normal path of descent (external inguinal ring > inguinal canal > abdominal)
- ectopic testis (testis found outside its normal path of descent) is most commonly located within a superficial pouch between the external oblique fascia and Scarpa’s fascia (Denis Browne pouch)
- differential diagnosis:
  - retractile testes
  - atrophic testes
  - disorders of sexual differentiation (bilateral impalpable gonads)

Epidemiology
- 2.7% of full term newborns
- 0.7-0.8% at 1 yr

Treatment
- orchiopexy
- hormonal therapy not proven to be of benefit over standard surgical treatment

Prognosis
- reduction in fertility
  - untreated bilateral cryptorchidism: ~100% infertility
  - paternity rates: 53%, 90%, and 93% in formerly bilateral cryptorchid, formerly unilateral cryptorchid, and normal men, respectively
- increased malignancy risk
  - intraabdominal > inguinal
  - surgical correction facilitates testicular monitoring and may reduce malignancy risk
- increased risk of testicular torsion (reduced by surgical correction)

Disorders of Sexual Differentiation

Definition
- formerly known as intersex disorders
- abnormal genitalia for chromosomal sex due to the undermasculinization of males or the virilization of females
- considered a social emergency

Classification
1. 46 XY DSD
   - defect in testicular synthesis of androgens
   - androgen resistance in target tissues
   - palpable gonad
2. 46 XX DSD
   - most due to CAH (21-hydroxylase deficiency most common enzymatic defect) → shunt in steroid biosynthetic pathway leading to excess androgens
   - undiagnosed and untreated CAH can be associated with life-threatening electrolyte abnormalities in the newborn (salt-wasting CAH)
3. ovotesticular DSD
4. mixed gonadal dysgenesis (46 XY/45 XO most common karyotype)
   - presence of Y chromosome → partial testis determination to varying degrees
Diagnosis
• thorough family Hx noting any consanguinity
• maternal Hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
• P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, stretched phallus length, position of urethral meatus
• laboratory tests
  ▪ plasma 17-OH-progesterone (after 36 h of life) → increased in 21-hydroxylase deficiency (CAH)
  ▪ plasma 11-deoxycortisol → increased in 11-β-hydroxylase deficiency
  ▪ basal adrenal steroid levels
  ▪ serum testosterone and DHT pre- and post-hCG stimulation (2,000 IU/d for 4 d)
  ▪ serum electrolytes
  ▪ chromosomal evaluation including sex karyotype
• U/S of adrenals, gonads, uterus, and fallopian tubes
• endoscopy and genitography of urogenital sinus

Treatment
• steroid supplementation as indicated (e.g. CAH)
• sex assignment after extensive family consultation
  ▪ must consider capacity for sexually functioning genitalia in adulthood, fertility potential, and psychological impact
• reconstruction of external genitalia between 6 and 12 mo
• long-term psychological guidance and support for both patient and family

Enuresis
• see Pediatrics, P9

Selected Urological Procedures

Bladder Catheterization
• catheter size measured by the French (Fr) scale – circumference in mm
• each 1 mm increase in diameter = approximately 3 Fr increase (standard size 16-18 Fr)
• should be removed as soon as possible to reduce the risk of UTI

Continuous Catheterization
• indications
  ▪ accurate monitoring of U/O
  ▪ relief of urinary retention due to medication, neurogenic bladder, or intravesical obstruction
  ▪ temporary therapy for urinary incontinence
  ▪ perineal wounds
  ▪ clot prevention (24-28 Fr) for CBI
  ▪ post-operative

Alternatives to Continuous Catheterization
• intermittent catheterization
  ▪ PVR measurement
  ▪ to obtain sterile diagnostic specimens for U/A, urine C&S
  ▪ management of neurogenic bladder or chronic urinary retention
• condom catheter
• suprapubic catheter

Causes of Difficult Catheterizations and Treatment
• patient discomfort → use sufficient lubrication (± xylocaine)
• collapsing catheter → lubrication as above ± firmer or larger catheter (silastic catheter)
• meatal/urethral stricture → dilate with progressively larger catheters/balloon catheter
• BPH → use coudé catheter as angled tip can help navigate around enlarged prostate
• urethral disruption/obstruction → filiform and followers or suprapubic catheterization
• anxious patient → anxiolytic medication

Complications of Catheterization
• infection: UTI
• meatal/urethral trauma
Circumcision

Definition
• removal of some or all of the foreskin from the penis

Epidemiology
• 30% worldwide
• frequency varies depending on geographic location, religious affiliation, socioeconomic classification

Medical Indications
• phimosis and recurrent paraphimosis
• recurrent UTIs (particularly in infants and in association with other urinary abnormalities)
• balanitis xerotica obliterans or other chronic inflammatory conditions

Contraindications
• unstable or sick infant
• congenital genital abnormalities (hypospadias)
• family Hx of bleeding disorders warrants laboratory investigation prior to circumcision

Complications
• bleeding
• infection
• penile entrapment, skin bridges
• fistula
• glans injury
• penile sensation deficits

Cystoscopy

Objective
• endoscopic inspection of the lower urinary tract (urethra, prostate, bladder, and ureteral orifices), samples for cytology
• scopes can be flexible or rigid

Indications
• gross hematuria
• LUTS (storage or voiding)
• urethral and bladder neck strictures
• bladder stones
• bladder tumour surveillance
• evaluation of upper tracts with retrograde pyelography (ureteric stents, catheters)

Complications
• during procedure
  ▪ bleeding
  ▪ anesthetic-related
  ▪ perforation (rare)
• post-procedure (short-term)
  ▪ infections, e.g. epididymo-orchitis (rare)
  ▪ urinary retention
• post-procedure (long-term)
  ▪ stricture

Circumcision Status and Risk of HIV and Sexually Transmitted Infections among Men who have Sex with Men: A Meta-Analysis

Purpose: To describe the association between male circumcision and HIV infection and other sexually transmitted infections (STIs) among men who have sex with men (MSM).

Methods: Meta-analysis of 15 studies (n=53,567)

Results: The associations between circumcision and HIV-positive and STIs were not statistically significant. Male circumcision had a protective association with HIV in studies of MSM conducted before the introduction of highly active anti-retroviral therapy.

Conclusions: There is insufficient evidence to support that male circumcision protects against HIV infection or other STIs.

Male Circumcision for Prevention of Heterosexual Acquisition of HIV in Men
Cochrane DB Syst Rev 2009;2:CD003362

Purpose: To evaluate the effectiveness and safety of male circumcision for preventing acquisition of HIV in heterosexual men.

Methods: The analyzed data is from three randomized controlled trials to assess the efficacy of male circumcision for preventing HIV acquisition in men in Africa.

Results: Medical male circumcision reduces the acquisition of HIV by heterosexual men (30%-66% over 24 mo).

Male Circumcision for Prevention of Heterosexual Acquisition of HIV in Men

Study: Guidelines by the American Academy of Pediatrics (AAP).

Recommendations: The American Academy of Pediatrics radically changed their position on male circumcision in 2012. The report from the AAP now states that the preventative health benefits outweigh the risks of the procedure and that the procedure is well-tolerated with adequate pain management and sterility. Stated benefits include the prevention of urinary tract infection, penile cancer, transmission of some sexually transmitted infections, including HIV. There is believed to be no effect on penile sexual function, sensitivity or sexual satisfaction. Acute complications are rare and more common if the procedure is done by an untrained provider.

Note: The Canadian Pediatric Society (CPS) has not yet updated their position on male circumcision since 1996, which stated that the CPS is opposed to routine circumcision. A new statement is expected soon.
Radical Prostatectomy

**Objective**
- the removal of the entire prostate and prostatic capsule via a lower midline abdominal incision, laparoscopically or robotically
  - internal iliac and obturator vessel lymph nodes may also be dissected and sent for pathology (dependent on risk: clinical stage, grade, PSA)
  - seminal vesicle vessels are also partially or completely removed

**Indications**
- treatment for localized prostate cancer

**Complications**
- immediate (intraoperative)
  - blood loss
  - rectal injury (extremely rare)
  - ureteral injury (extremely rare)
- perioperative
  - lymphocele formation
- late
  - moderate to severe urinary incontinence (3-10%)
  - mild urinary incontinence (20%)
  - ED (~50%, depending on whether one, both, or neither of the neurovascular bundles are involved in extracapsular extension of tumour)

Transurethral Resection of the Prostate

**Objective**
- to partially resect the periurethral portion of the prostate (transition zone) to decrease symptoms of urinary tract obstruction
- accomplished via a transurethral (cystoscopic) approach using an electrocautery loop, irrigation (glycine), and illumination

**Indications**
- obstructive uropathy (large bladder diverticula, renal insufficiency)
- refractory urinary retention
- recurrent UTIs
- recurrent gross hematuria
- bladder stones
- intolerance/failure of medical therapy

**Complications**
- acute
  - intra- or extraperitoneal rupture of the bladder
  - rectal perforation
  - incontinence
  - incision of the ureteral orifice (with subsequent reflux or ureteral stricture)
  - hemorrhage
  - epididymitis
  - sepsis
  - transurethral resection syndrome (also called “post-TURP syndrome”)
    - caused by absorption of a large volume of the hypotonic irrigation solution used, usually through perforated venous sinusoids, leading to a hypervolemic hyponatremic state
    - characterized by dilutional hyponatremia, confusion, nausea, vomiting, HTN, bradycardia, visual disturbances, CHF, and pulmonary edema
    - treat with diuresis and (if severe) hypertonic saline administration
- chronic
  - retrograde ejaculation (>75%)
  - ED (5-10% risk increases with increasing use of cautery)
  - incontinence (<1%)
  - urethral stricture
  - bladder neck contracture

**Study**: A systematic review to compare perioperative outcomes, positive surgical margin (PSM) rates, and functional outcomes in retropubic radical prostatectomy (RRP) laparoscopic RP (LRP) and robot-assisted radical prostatectomy (RARP).

**Methods**: Medline database was searched. Weighted means (based on number of participants in each study) were calculated for all outcomes.

**Results**: 58 articles were reviewed. LRP and RARP were associated with better perioperative outcomes compared to RRP. LRP and RARP had similar post-operative complication rates ranging from 10.3-10.98%. RARP had a lower overall PSM rate than LRP, and RRP. RARP had the highest continence rate and mean potency rates.

**Conclusion**: In high-volume centers, RRP, LRP and RARP are safe options for treating patients with localized prostate cancer. LRP and RARP are associated with better perioperative outcomes and RARP showed lower PSM rates, higher potency and continence compared to RRP and LRP.
Extracorporeal Shock Wave Lithotripsy

Objective
- to treat renal and ureteral calculi (proximal, middle or distal) which cannot pass through the urinary tract naturally
- shockwaves are generated and focused onto stone → fragmentation, allowing stone fragments to pass spontaneously and less painfully

Indications
- potential first-line therapy for renal and ureteral calculi <2.5 cm
- individuals with calculi in solitary kidney
- individuals with HTN, DM or renal insufficiency
*patient preference and wait-times play a large role in stone management

Contraindications
- acute UTI or urosepsis
- bleeding disorder or coagulopathy
- pregnancy
- obstruction distal to stone

Complications
- bacteriuria
- bacteremia
- post-procedure hematuria
- ureteric obstruction (by stone fragments)
- peri-nephric hematoma

<td>Tricyclic antidepressant</td>
<td>Sympathomimetic effects: urinary sphincter contraction Anticholinergic effects: detrusor relaxation</td>
<td>Stress and urge incontinence</td>
<td>As above Weight gain Orthostatic hypotension Prolonged PR interval</td>
</tr>
</tbody>
</table>

Note: All anti-cholinergics are equally effective and long-acting formulations are better tolerated. Newer muscarinic M3 receptor specific agents (solifenacin, darifenacin) are equally efficacious as older drugs, however, RCTs based on head-to-head comparison to long acting formulations are lacking.

Peripheral Arterial Disease

Chronic Arterial Occlusion/Insufficiency

Definition
- chronic ischemia due to inability of the arterial supply to meet cellular metabolic demands

Etiology
- predominantly due to atherosclerosis (for pathogenesis, see Cardiology, C26); primarily occurs in the lower extremities

Risk Factors
- major: smoking, DM
- minor: HTN, hyperlipidemia, obesity, sedentary lifestyle, PMHx or FMHx CAD/CVD

Clinical Features
- claudication - must differentiate vascular from neurogenic claudication (see Table 1)
  1. pain with exertion: usually in calves or any exercising muscle group
  2. relieved by short rest: 2-5 min, and no postural changes necessary
  3. reproducible: same distance to elicit pain, same location of pain, same amount of rest to relieve pain
- critical limb ischemia (CLI)
  1. includes rest pain, night pain, tissue loss (ulceration or gangrene)
  2. pain most commonly over the forefoot, waking person from sleep, and often relieved by hanging foot off bed
  3. ankle pressure <40 mmHg, toe pressure <30 mmHg, ABI <0.40
- pulses may be absent at some locations, bruits may be present
- signs of poor perfusion: hair loss, hypertrophic nails, atrophic muscle, skin ulcerations and infections, slow capillary refill, prolonged pallor with elevation and rubor on dependency, venous troughing (collapse of superficial veins of foot)
- other manifestations of atherosclerosis: CVD, CAD, impotence, splanchnic ischemia

Differential Diagnosis of Claudication

Vascular
- Atherosclerotic disease
- Vasculitis (e.g. Buerger’s disease, Takayasu’s arteritis)
- Diabetic neuropathy
- Venous disease (e.g. DVT, varicose veins)
- Popliteal entrapment syndrome (e.g. Baker’s cyst, tumour)

Neurogenic
- Neurospinal disease (e.g. spinal stenosis)
- Reflex sympathetic dystrophy

MSK
- OA
- Rheumatoid arthritis/connective tissue disease
- Remote trauma

Investigations
- non-invasive
- routine blood work, fasting metabolic profile
- ABI: take highest brachial and highest ankle (dorsalis pedis artery or posterior tibial artery) pressures for each side generally
  - ABI <0.90 abnormal, rest pain appears at <0.30 (see Table 3)
- CTA and MRA
  - excellent for large arteries (aorta, iliac, femoral, popliteal) may have difficulty with tibial arteries (especially in the presence of disease)
  - require IV injection of nephrotoxic contrast (iodinated contrast for CT, gadolinium for MR)
  - used primarily for planning interventions
- invasive arteriography: superior resolution to CTA/MRA, better for tibial arteries, can be done intraoperatively

</tr>
</tbody>
</table>

Treatment
- conservative
  - risk factor modification (smoking cessation, HbA1c control, treatment of HTN, hyperlipidemia (statin), antiplatelet therapy [ECASA])
  - exercise program (30 min 3x/wk): improves collateral circulation, oxygen extraction at the muscle level
  - foot care (especially in DM): keep wounds clean/dry, avoid trauma and pressure on wounds
- pharmacotherapy
  - antiplatelet agents (e.g. ECASA, clopidogrel)
  - cilostazol (cAMP-phosphodiesterase inhibitor with antiplatelet and vasodilatory effects): improves walking distance for some patients with claudication (not available in Canada)
- surgical/endovascular
  - indications: severe lifestyle impairment, vocational impairment, critical ischemia
  - surgical options
    - endovascular (stenting/angioplasty)
    - endarterectomy: removal of plaque and repair with patch (usually distal aorta or common/profunda femoral)
    - bypass graft sites: aortofemoral, axillofemoral, femoropopliteal, distal arterial – graft choices: vein graft (reversed or in situ), synthetic (polytetrafluoroethylene graft (e.g. Gore-Tex®) or Dacron®)
    - amputation: if not suitable for revascularization, persistent serious infections/gangrene

Prognosis
- claudication: conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 yr, <4% will require amputation
- for patients with CLI (rest pain, night pain, ulceration or gangrene): high risk of limb loss (which carries 25% risk of death at 1 yr)

Acute Arterial Occlusion/Insufficiency

Definition
- acute occlusion/rupture of a peripheral artery, usually without a history of claudication
- urgent management required
  - skeletal muscle can tolerate 6 h of ischemia before or irreversible damage and myonecrosis result, exception is in acute-on-chronic occlusion, because the build up of collaterals allows time to investigate
  - tends to be lower extremity > upper extremity; femoropopliteal > aortoiliac
Etiology and Risk Factors

- embolism (examples of pro-embolic conditions are cardiac arrhythmias, endocarditis, and arterial aneurysms)
- existing atherosclerotic plaques (ie chronic PAD) can rupture causing occlusion
- hypercoagulable states can contribute to arterial thrombosis

Clinical Features

Investigations

- history and physical exam are essential: depending on degree of ischemia one may have to forego investigations and go straight to the operating room
- ABI: extension of physical exam, easily performed at bedside
- ECG, troponin: rule out recent MI or arrhythmia
- CBC: rule out leukocytosis, thrombocytosis or recent drop in platelets in patients receiving heparin
- PT/INR: patient anticoagulated/sub-therapeutic INR
- Echo: identify wall motion abnormalities, intracardiac thrombus, valvular disease, aortic dissection (Type A)
- CT angiogram: underlying atherosclerosis, aneurysm, aortic dissection
- conventional catheter based angiography: can be obtained in OR; prelude to thrombolytics

</tr>
</tbody>
</table>

Treatment

- immediate heparinization with 5000 IU bolus and continuous infusion to maintain PTT >60 s
- if impaired neurovascular status: emergent revascularization
- if intact neurovascular status: time for work up (including angiogram)
- definitive treatment
  - embolus: embolectomy
  - thrombus: thrombectomy ± bypass graft ± endovascular therapy
  - irreversible ischemia (complete loss of power or sensation, absent venous and arterial dopplers, rigor): primary amputation
- identify and treat underlying cause
- continue heparin post-operatively, start warfarin post-operative day 1 x 3 mo depending on underlying etiology

Complications

- compartment syndrome with prolonged ischemia; requires 4-compartment (anterior/lateral/superficial and deep posterior) fasciotomy
- risk of arrhythmia and death with reperfusion injury
- renal failure and multi-organ failure due to toxic metabolites from ischemic muscle

Prognosis

- 12-15% mortality rate
- 5-40% morbidity rate (amputation)
Aortic Disease

Aortic Dissection

Definition
- tear in aortic intima allowing blood to dissect into the media
- Stanford classification: Type A (involve the ascending aorta) vs. Type B (do not)
- DeBakey Classification
  - Type I: involves the ascending aorta, aortic arch, and descending aorta
  - Type II: confined to the ascending aorta
  - Type III: confined to the descending aorta distal to the left subclavian artery
- acute <2 wk (initial mortality 1% per hour for Type A dissections)
- chronic >2 wk (mortality levels up to 75-80%)

Etiology
- most common: HTN → degenerative/cystic changes → damage to aortic media
- other: connective tissue disease (e.g. Marfan’s, Ehlers-Danlos), cystic medial necrosis, atherosclerosis, congenital conditions (e.g. coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection (e.g. syphilis), trauma, arteritis (e.g. Takayasu’s)

Epidemiology
- incidence of 5.2 in 1,000,000
- M:F = 3:2:1
- small increased incidence in African-Canadians (related to higher incidence of HTN)
- lowest incidence in Asians
- peak incidence 50-65 yr old; 20-40 yr old with connective tissue diseases

Clinical Features
- sudden onset tearing chest pain that radiates to back with:
  - HTN (75-85% of patients)
  - asymmetric BPs and pulses between arms (>30 mmHg difference indicates poor prognosis)
  - ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotid (ischemic stroke, Horner’s syndrome), splanchic (mesenteric ischemia), renal (AKI), peripheral (ischemic leg), intercostal vessels (spinal cord ischemia)
  - “unseating” of aortic valve cusps (new diastolic murmur in 20-30%) in Type A dissection
  - rupture into pleura (dyspnea, hemothorax) or peritoneum (hypotension, shock) or pericardium (cardiac tamponade)
  - syncope

Investigations
- CXR
  - pleural cap (pleural effusion in lung apices)
  - widened mediastinum
  - left pleural effusion with extravasation of blood
- TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta
- ECG: LVH ± ischemic changes, pericarditis, heart block
- CTA (gold standard), aortography, MRA: 100% sensitive and specific
- blood work: lactate (elevated in ischemic gut, shock), amylase (rule out pancreatitis), troponin (rule out MI)

Treatment
- pharmacologic
  - β-blocker to lower BP and decrease cardiac contractility
  - use nondihydropyridine CCB if there is a clear contraindication to β-blockers
  - target sBP of 110 mmHg and HR <60 bpm
  - ACEI and/or other vasodilators if insufficient BP or HR control
- surgical
  - urgent surgical consult if thoracic aortic dissection diagnosed or highly suspected
  - Type A to cardiac surgery, Type B to vascular surgery
  - resection of segment with intimal tear
  - reconstitution of flow through true lumen
  - replacement of the affected aorta with prosthetic graft
  - correction of any predisposing factors
  - post-operative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
  - 2/3 of patients die of operative or post-operative complications

Figure 3. Aortic anatomy
**Aortic Aneurysm**

**Definition of Aneurysm**
- localized dilatation of an artery having a diameter at least 1.5x that of the expected normal diameter
  - true aneurysm: involving all vessel wall layers (intima, media, adventitia)
  - false aneurysm (also known as pseudo-aneurysm): disruption of the aortic wall or the anastomotic site between vessel and graft with containment of blood by a fibrous capsule made of surrounding tissue
- aneurysms can rupture, thrombose, embolize, erode, and fistulate

**Classification**
- thoracic aortic aneurysm (TAA): ascending, transverse arch, descending
- thoracoabdominal
- abdominal aortic aneurysm (AAA): 90-98% are infrarenal
  - suprarenal: involves one or more visceral arteries, but does not involve the chest
  - pararenal: renal arteries arise from aneurysmal aorta, but the SMA origin is not aneurysmal
  - juxtarenal: the renal arteries originate from normal aorta, but are immediately adjacent to aneurysmal aorta (there is no nonaneurysmal aorta distal to the origin of the renal arteries)
- infrarenal: The aneurysm originates distal to the renal arteries (there is nonaneurysmal aorta distal to the origins of the renal arteries)

**Etiology**
- degenerative (atherosclerotic)
- traumatic
- mycotic (*Salmonella, Staphylococcus*, usually suprarenal aneurysms)
- connective tissue disorder (Marfan syndrome, Ehlers-Danlos syndrome)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic aneurysms are associated with bicuspid aortic valve
- risk factors: smoking, HTN, age >70, family history

**Epidemiology**
- incidence 4.7 to 31.9 per 100,000 for AAA and 5.9 per 100,000 for TAA
- high risk groups
  - ≥65 yr
  - M:F = 3.8:1
  - PVD, CAD, CVD
  - family history of AAA

**Figure 4. Classification of aortic dissection** (black arrow indicates where the dissection begins)

- **DeBakey:**
  - Type I: 50%
  - Type II: 35%
- **Stanford:**
  - Type A
  - Type B

**ACC/AHA 2005 Guidelines** define an AAA when the minimum AP diameter of abdominal aorta ≥3.0 cm

**Figure 5. Classification of aneurysms**
Clinical Features
- associated diseases: HTN, PVD, CAD, COPD, renal insufficiency
- most commonly in the abdominal aorta (50% abdominal aorta, 40% thoracic aorta, 10% ascending aorta)
- common presentation: due to acute expansion or rupture
  - syncpe
  - pain (chest, abdominal, flank, back)
  - hypotension
  - palpable pulsatile mass above the umbilicus
  - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemesis (indicates thoracic or thoracoabdominal aortic aneurysm)
  - distal pulses may be intact
- 75% asymptomatic (discovered incidentally)
- uncommon presentations
  - ureteric obstruction and hydronephrosis (often with inflammatory aortic aneurysm)
  - gastrointestinal bleed (duodenal mucosal hemorrhage, aortoduodenal fistula)
  - aortocaval fistula
  - distal embolization (blue toe syndrome) occurs in <1% of AAAs

Investigations
- blood work: CBC, electrolytes, urea, creatinine, PTT, INR, type and cross blood
- Doppler/duplex (rule out vascular tree aneurysms elsewhere, e.g. popliteal)
- aortogram (only for EV AR)
- CT with contrast (accurate visualization, size determination, EV AR planning)
- abdominal U/S (100% sensitive, up to ±0.6 cm accuracy in size determination)
- investigations
  - common presentation: due to acute expansion or rupture
  - most commonly in the abdominal aorta (50% abdominal aorta, 40% thoracic aorta, 10% thoracoabdominal aorta)
Carotid Stenosis

Definition
• narrowing of the internal carotid artery lumen due to atherosclerotic plaque formation, usually near common carotid bifurcation into internal and external carotids

Risk Factors
• for atherosclerosis: HTN, smoking, DM, CVD or CAD, dyslipidemia

Clinical Features
• may be asymptomatic
• symptomatic stenosis may present as TIA, RIND, or stroke
• retinal insufficiency or infarct permanently or temporarily (ipsilateral amaurosis fugax), (see Ophthalmology, OP23)
• MCA contralateral occlusive symptoms

Investigations
• CBC, PTT/INR (hypercoagulable states)
• fundoscopy: cholesterol emboli in retinal vessels (Hollenhorst plaques)
• auscultation over carotid bifurcation for bruits (do not correlate with degree of stenosis)
• carotid duplex: determines severity of disease (mild/moderate/severe stenosis of occlusion)
• angiogram: “gold standard” but invasive and 1/200 risk of stroke (i.e. only used intraoperatively)
• MRA: safer than angiogram, may overestimate stenosis
• CTA

Treatment
• control of HTN, lipids, DM
• antiplatelet agents (ASA ± dipyridamole, clopidogrel) ~25% relative risk reduction
• carotid endarterectomy (generally if symptomatic and >70% stenosis)
• endovascular angioplasty ± stenting

Prognosis

Prevention of Disabling and Fatal Strokes by Successful Carotid Endarterectomy in Patients Without Recent Neurological Symptoms: Randomized Controlled Trial Lancet 2004;363:1491-1502
Study: Asymptomatic Carotid Surgery Trial (ACST), a RCT with follow-up at 5 yr.
Patients: 3,120 asymptomatic patients with significant carotid artery stenosis were randomized equally between immediate carotid endarterectomy (CEA) and indefinite deferral of CEA and were followed for up to 5 yr (mean 3.4 yr).
Main Outcome: Any stroke (including fatal or disabling).
Conclusions: In asymptomatic patients with significant carotid artery stenosis, immediate CEA reduced the net 5-yr stroke risk from about 12% to about 6%. Half of this 5-yr benefit involved disabling or fatal strokes.
Peripheral Venous Disease

Deep Venous Thromboembolism

- see Hematology, H35

Superficial Venous Thrombosis

Definition
- thrombosis of a superficial vein; usually spontaneous but can follow venous cannulation

Etiology
- infectious: suppurative phlebitis (complication of IV cannulation; associated with fever/chills)
- trauma
- inflammatory: varicose veins, migratory superficial thrombophlebitis, Buerger’s disease, SLE
- hematologic: polycythemia, thrombocytosis
- neoplastic: occult malignancy (especially pancreatic)
- idiopathic

Clinical Features
- most common in greater saphenous vein and its tributaries
- pain and cord-like swelling along course of involved vein
- areas of induration, erythema, and tenderness correspond to dilated and often thrombosed superficial veins
- complications
  - simultaneous DVT (up to 20% of cases), PE (rare unless DVT)
  - recurrent superficial thrombophlebitis

Investigations
- non-invasive tests (e.g. Doppler) to exclude associated DVT

Treatment
- conservative
  - moist heat, compression bandages, mild analgesic, anti-inflammatory and anti-platelet (e.g. ASA), LMWH, ambulation
- surgical excision of involved vein
  - indication: failure of conservative measures (symptoms that persist over 2 wk)
  - suppurative thrombophlebitis: broad-spectrum IV antibiotics and excision

Varicose Veins

Definition
- distention of tortuous superficial veins resulting from incompetent valves in the deep, superficial, or perforator systems

Etiology
- primary varicosities: venous valve incompetence or obstruction
  - contributing factors: increasing age, systemic hormonal contraceptive use, prolonged standing, pregnancy, obesity
- secondary varicosities: DVT, malignant pelvic tumours with venous compression, congenital anomalies, arteriovenous fistulae

Epidemiology
- primary varicose veins are the most common form of venous disorder of lower extremity
- 10-20% of population

Clinical Features (Not Correlated with Varicosity Size)
- diffuse aching, fullness/tightness, nocturnal cramping
- aggravated by prolonged standing (end of day), premenstrual
- visible long, dilated and tortuous superficial veins along thigh and leg (greater or short saphenous veins and tributaries)
- ulceration, hyperpigmentation, and induration (secondary varicosities)
• Brodie-Trendelenburg test (valvular competence test)
  - with patient supine, raise leg and compress saphenous vein at thigh, have patient stand –
    if veins fill quickly from top down then incompetent valves; use multiple tourniquets to
    localize incompetent veins

Complications
• recurrent superficial thrombophlebitis
• hemorrhage: external or subcutaneous
• ulceration, eczema, lipodermatosclerosis, and hyperpigmentation

Treatment
• largely a cosmetic problem
• conservative: elevation of leg and/or elastic compression stockings
• surgical: high ligation and stripping of the long saphenous vein and its tributaries, ultrasound-
guided foam sclerotherapy, endovenous laser therapy
• indications for surgery: symptomatic varix (pain, bleeding, recurrent thrombophlebitis), tissue
  changes (hyperpigmentation, ulceration), failure of conservative treatment, cosmetics

Prognosis
• benign course with predictable complications
• almost 100% symptomatic relief with treatment if varicosities are primary
• good cosmetic results with treatment
• significant post-operative recurrence

Chronic Venous Insufficiency

Definition
• venous insufficiency and skin damage

Etiology
• calf muscle pump dysfunction and valvular incompetence (valvular reflux) due to phlebitis,
  varicosities, or DVT
• venous obstruction

Clinical Features
• pain (most common), ankle and calf edema – relieved by foot elevation
• pruritus, brownish hyperpigmentation (hemosiderin deposits)
• stasis dermatitis, subcutaneous fibrosis if chronic (lipodermatosclerosis)
• ulceration: shallow, above medial malleolus, weeping (wet), painless, irregular outline
• signs of DVT/varicose veins/thrombophlebitis

Investigations
• Doppler U/S (most commonly used)
• venography or ambulatory venous pressure measurement (not often used)

Treatment
• conservative
  • elastic compression stockings, ambulation, periodic rest-elevation, avoid prolonged standing
  • ulcers: multilayer compression bandage, antibiotics prn
  • endovenous: laser or radiofrequency ablation, or foam sclerotherapy
• surgical
  • if conservative measures fail, or if recurrent/large ulcers
  • surgical ligation of perforators in region of ulcer (GSV/LSV ligation and stripping)
**Lymphedema**

**Definition**
- obstruction of lymphatic drainage resulting in edema with high protein content

**Etiology**
- primary
  - Milroy’s syndrome: congenital hereditary lymphedema
  - lymphedema praecox (75% of cases): starts in adolescence
  - lymphedema tarda: starts >35 yr
- secondary
  - infection: filariasis (#1 cause worldwide), post-operative
  - malignant infiltration: axillary, groin or intrapelvic
  - radiation/surgery (axillary, groin lymph node removal): #1 cause in North America

**Clinical Features**
- classically non-pitting edema
- impaired limb mobility, discomfort/pain, psychological distress

**Treatment**
- avoid limb injury (can precipitate or worsen lymphedema)
- skin hygiene
  - daily skin care with moisturizers
  - topical treatment of fungal infection; systemic treatment of bacterial infection
- external support
  - intensive: compression bandages
  - maintenance: lymphedema sleeve
- exercise
  - gentle daily exercise of affected limb, gradually increasing ROM
  - must wear a compression sleeve/bandages when doing exercises
- massage and manual lymph drainage therapy

**Prognosis**
- if left untreated becomes resistant to treatment due to subcutaneous fibrosis
- cellulitis causes rapid increase in swelling; can lead to sepsis and death

For 32 years, Toronto Notes has been a premier study resource for the Canadian MCCQE and USMLE Step II medical licensing exams. This edition provides concise and comprehensive information on the objectives covered by these exams, including the most recent best practice guidelines and up-to-date trials for clinical practice. Toronto Notes is an excellent resource for clinical rotations and this text contains 30 subject-specific chapters:

- Anesthesia and Perioperative Medicine
- Cardiology and Cardiac Surgery
- Clinical Pharmacology
- Dermatology
- Emergency Medicine
- Endocrinology
- Ethics, Legal, and Organizational Medicine
- Family Medicine
- Gastroenterology
- General Surgery
- Geriatric Medicine
- Gynecology
- Hematology
- Infectious Diseases
- Medical Imaging
- Nephrology
- Neurology
- Neurosurgery
- Obstetrics
- Ophthalmology
- Orthopedics
- Otolaryngology
